Comment—We feel that in both these cases the failure of the initial course of treatment to eliminate the infection completely was probably due to the long delay in starting treatment, together with the unusual structure and blood-supply of the bones affected, which led to extensive sequestration We also regret that the first operation for removal of sequestra and tooth-buds from the mandible of case 30 was delayed until 30 days after admission to hospital, by which time the initial satisfactory clinical response to the antibiotic had been shown to be illusory by the appearance of a further spontaneous discharge of pus It seems probable that this operation could have been done much sooner, with safety and benefit, had the need for it been appreciated sooner

Case 25 (mild) was admitted 2 days after developing signs of osteitis of the right maxilla She was treated with aureomycin from the start, and within 4 days of admission 8 c cm of pus had been aspirated from the right orbit, and there had been a spontaneous discharge of pus into the mouth from the right bucco alveolar sulcus The *Staph aureus* cultured was partially resistant to penicillin but sensitive to aureomycin, with which drug treatment was continued in diminishing dosage for 67 days

3 weeks later, however, she developed swelling of the right cheek and lower lid and was given a second course of aureomycin, which lasted 106 days During the subsequent $1^1/_2$ years all has been well, apart from the fact that the right

upper first premolar is poorly enamelled and has only partly erupted

Comment —In this case the reason for the failure of the *first course of treatment is less clear Probably it would have been wiser to explore the spontaneous sinus into the mouth when it first developed, with a view to removing* any infected tooth-buds, but this was never seriously contemplated, because the opening healed in a few days

Case 15 (mild) received three short courses of antibiotic treatment during the first 4 weeks of life (penicillin for 5 days, and chloramphenicol for 6 days and again for 3 days) The indication was an inflammatory swelling over the chest wall which was first seen in the Maternity Hospital at the age of 7 days and thought to be a primary soft tissue abscess The course of penicillin was started at the age of 8 days, and the swelling was also incised twice during the first month After each course of treatment the local signs recurred, but it was not until the baby was nearly 6 weeks old that an underlying osteitis was suspected when the abscess recurred for the third time and burst spontaneously She was then treated with aureomycin for 3 weeks, but 3 weeks later there was a further recurrence, and this time aureomycin treatment was continued for 6 weeks

About 6 weeks later, however, she had yet another recurrence (her fifth) A *Staph aureus* sensitive to penicillin and aureomycin was recovered from the pus in her first recurrence (at the age of 17 days), her third (at the age of 32 days), and her fifth (at the age of 6 months), in her fourth recurrence, however (at the age of 3 months), the *Staph aureus* was resistant to penicillin Since no penicillin had been used since the 2nd week of life, this organism was thought probably to have been a contaminant, and the fifth recurrence was treated with penicillin for 6 weeks During the subsequent 4 years there has been no further trouble

Comment —This case is included as one of those in which a short course of the appropriate antibiotic did not eliminate the infection Penicillin was used at the start but for only 5 days, and a whole series of recurrences followed, yet, about 6 months later, when the same antibiotic was used again but this time for 6 weeks, an apparent cure followed But there is the complicating factor that in the interval two long courses of aureomycin had been given, lasting 3 weeks and 6 weeks, without success This may be a simple question of a bacteriostatic drug's being less effective than a bactericidal one, but we have wondered whether it was partly a question of dosage In treating acute osteitis with penicillin it it has long been the practice to use much larger doses, and greater frequency of administration, than in treating soft tissue infections This practice is based on sound theory and supported by experience Yet with other antibiotics the standard dosage has been routinely used even in acute osteitis, both by ourselves in the past and by others (Dennison 1955a, case 1) We have more recently adopted the practice, when using a tetracycline antibiotic, of starting with a dosage of about 50 mg per lb of body weight daily, administered 3 hourly by mouth and later reducing the frequency of administration and the dosage if a favourable clinical response is achieved We have not yet had enough experience of this method to judge its effectiveness in preventing recurrences

The anomalous bacteriological findings in this case represent the only possible example of a change of antibiotic sensitivity during the course of observation in any case in this series

Summary

Evidence from the case histories of 40 cases of neonatal osteitis (21 "severe" and 19 "mild") confirms that this disease can still produce death or crippling deformity

It also confirms that really early antibiotic treatment, in a suitable hospital may prevent these serious complications The earliest signs of the disease are, in order of frequency local swelling excessive irritability, pseudo paralysis of a limb, and the signs of a severe general infection

Prolonged antibiotic treatment (for a minimum of thre weeks, and an average of five weeks) is shown to b effective in preventing recurrences, as compared wit *short courses of treatment Of 31 cases* "adequately" treated, 5 had one or more recurrences of 7 case inadequately treated, 6 had one or more recurrence

We are most grateful to our colleagues, who allowed us to treat their cases so that we might gain greater experience of this disease and to Dr C A Green, in whose department was done the bacteriological work on which we relied so heavily in deciding which antibiotics to use

PITUITARY NECROSIS DUE TO IMPLANTS OF RADIOACTIVE GOLD AND YTTRIUM

Stretton Young
M B St And

From the Clinico Pathological Laboratories of the Imperial Cancer Research Fund

It is well known that some cases of mammary and prostatic carcinoma respond favourably to removal of the steroid-producing endocrine glands When these cases relapse, a further period of improvement can sometimes be induced by removal or destruction of the adenohypophysis Other cases may be treated by hypophysectomy without previous ablation therapy, and in some of these also the disease is arrested

In successfully treated cases it is believed that the tumour is stimulated to proliferate by one or more of the protein hormones from the pars anterior of the pituitary gland, and deprivation of these hormones leads to arrest of tumour growth or even to its regression

The difficulties encountered during the operation of hypophysectomy have led to the introduction of techniques for destroying the pituitary In one of these the destructive material is a radioactive isotope which is introduced into the pituitary through a cannula passing through the nose and the sphenoidal sinus

This paper contains a description of structural changes in the pituitary gland following implantation of the two radioactive isotopes ^{198}Au and ^{90}Y

Materials and Methods

Pituitary glands were obtained at autopsy from 14 patients who had previously received radioactive pituitary implants for mammary or prostatic carcinoma The glands were usually fixed in Helly's fluid, but cold formol saline solution followed by secondary fixation in Helly's fluid was also employed

Drawings were made of the shape of the gland and of the position and orientation of any visible implants The implants were then removed and the tissue trimmed so that the plane of the section would cross the axis of the implant at right angles

Three types of radioactive material had been used

(1) Radioactive gold (^{198}Au) grains cylindrical in shape measuring 0 8 × 2 5 mm The outer 0 1 mm is a non-radioactive screen of platinum which reduces the β irradiation

(2) Radioactive gold (^{198}Au) rods, cylindrical in shape and measuring 0 8×5 mm No platinum screen was present, thus the ratio of β to γ irradiation was considerably greater than in the screened variety

The activity of these implants is given in equivalent millicuries (mC) of radon, and the dose of γ irradiation in r units

(3) Yttrium oxide pellets, cylindrical in shape and measuring 1 3×3 95 mm (but subject to slight variations in size) These emit β irradiation only

TABLE II—RESULTS OBTAINED WITH RADIOACTIVE GOLD RODS

Fig no	Radon equivalent per rod (mC)	No of rods	Duration of action (days)	Effective activity (mC)	γ r at edge of necrotic area	Radius of necrosis (mm)
7	1 58	3	33	1 58	80 000	1 34
8	0 81	3	150	0 81	77 100	1 00
9	4 57	3	95	4 57	197,400	1 50

Results

Histological sections in a plane at right angles to the long axis of the implants were photographed at low magnification The photomicrographs were used to prepare line drawings in which necrotic areas are shown in black The plane of the section is indicated in the diagram accompanying each drawing Only ten of the fourteen pituitary glands examined have been illustrated by line drawings, the remaining four were technically unsuitable for presentation in this manner

TABLE III—RESULT OBTAINED WITH RADIOACTIVE YTTRIUM

Fig no	Activity (mC of ^{90}Y)	No of pellets	Duration of action	Effective activity (mC)	Radius of necrosis (mm)
10	4 5*	1	28 days	4 5	4

* This is the absolute activity of the pellet in mC of ^{90}Y as determined by 4π counting

The sections have been chosen to show the result of individual implants rather than their combined effect, and no attempt has been made to measure the total amount of destruction

Figs 1–6 illustrate the necrosis obtained in six cases in which grains of radioactive gold (^{198}Au) screened by 0 1 mm of platinum were used These results are summarised in table I

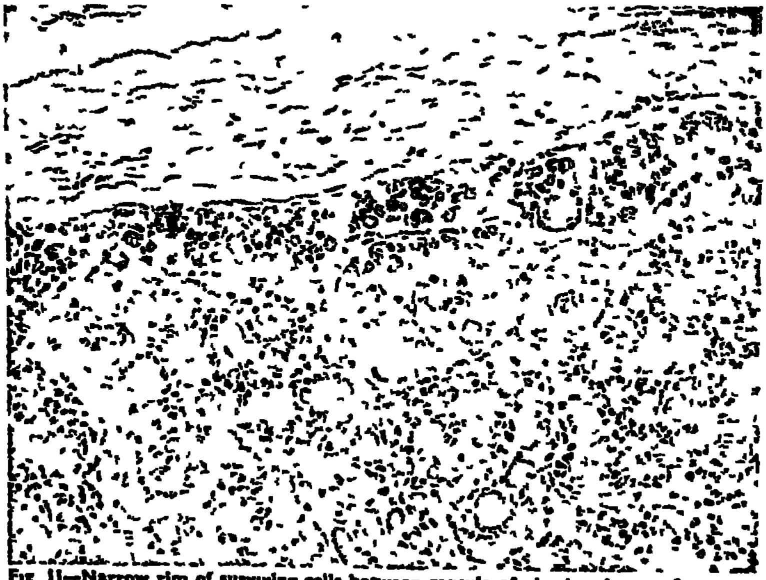

Fig 11—Narrow rim of surviving cells between capsule of gland and area of necrosis (Hæmatoxylin and eosin 200)

It would be of great value if some estimate could be made of the capacity of surviving pituitary tissue to regenerate Mitotic activity has been reported in the pituitary glands of animals after injury and hormone interference, and replacement may be complete if destruction be not too extreme (Cameron 1952) In numerous sections of irradiated pituitary glands, ranging from slight to almost total destruction, and from 31 hours' to 150 days' duration, I have not observed any evidence of mitosis

Possibly the delay between death and fixation of the tissue in these cases has allowed the mitotic process to complete itself before fixation This seems an improbable explanation in view of the fact that mitotic figures can be found in other tissues taken at autopsy It is more likely that the surviving pituitary cells have received sufficient irradiation to delay or to prevent their division

Conclusions

In this series of 14 cases, implants of radioactive gold (^{198}Au) and yttrium (^{90}Y) did not cause complete necrosis of the pituitary

A minimum of about 70,000r of γ irradiation appears to be necessary to cause necrosis in most parts of the pituitary gland

Cells adjacent to the capsule and those around blood-vessels were more resistant to radionecrosis than were those elsewhere

Chromophobe, eosinophil, and basophil cells appeared to be equally susceptible to the necrosing effects of γ and β irradiation

On the basis of the absence of mitotic activity in the apparently undamaged areas of the pituitary, there was no evidence of regeneration

I am grateful to Mr J D Fergusson, director of the Institute of Urology (University of London), Dr L M Franks, Dr R C B Pugh, and Dr C S Treip for access to material, and to Mr E V Willmott and Mr J D Gilbert for technical assistance Dr N R MacKay has given me valuable advice on matters relating to radiotherapy

Phenylketonuria is an inborn error of metabolism characterised by a severe degree of mental deficiency, by the excretion of phenylpyruvic acid in the urine, and by certain bodily features, of which fair hair is the most noticeable

There are several excellent accounts of the condition (Jervis 1937, 1938, Penrose 1946, Cowie 1951a and b), so only a brief survey will be given here Of mental defectives admitted to institutions about 0 5% suffer from the disorder, which is transmitted by a single recessive gene Fundamentally, there is a failure of hydroxylation of phenylalanine to tyrosine in the liver (Jervis 1947, 1953, Udenfriend and Bessman 1953, Armstrong and Shaw 1955) This results in a high plasma concentration of phenylalanine and the presence of many abnormal metabolites in the urine, of which phenylpyruvic acid is the best known (for biochemical review see Dalgliesh 1955) Although the defective hydroxylation of phenylalanine to tyrosine may account for the deficient pigmentation, it has provided no explanation for the other main clinical finding of mental deficiency The intelligence quotient (I Q) in these patients correlates neither with the level of phenylalanine in the blood nor with phenylpyruvic acid excretion in the urine (Borek et al 1950, Jervis 1950) It has been claimed that there is a correlation between the I Q and the amount of phenylpyruvic acid in the plasma , but this correlation is a positive one plasma levels of phenylpyruvic acid increasing with I Q and is probably an indication of the state of nutrition (Jervis 1952) Nevertheless various workers have treated affected children with a low-phenylalanine diet for long periods and in general have reported some improvement both in intelligence and in physical condition (Bickel et al 1953, Armstrong and Tyler 1955, Woolf et al 1955) Armstrong and Tyler (1955) conclude that " it seems probable that unknown and possibly complex factors other than the known defect in phenylalanine oxidation operate in conjunction with it and contribute to the mental defect "

Recently, Armstrong and Robinson (1954a and b) have offered evidence of abnormal indole metabolism in phenylketonuria, demonstrating the presence of indolelactic acid (I L A) in the urine of affected patients They also claimed, from paper-chromatographic studies, that there was a decreased urinary excretion of 5-hydroxyindoleacetic acid (5 H I A A) in some of their patients Their findings were confirmed by Ferrari and his colleagues (1955)

5-H I A A is known to be a metabolite of 5-hydroxytryptamine (5-H T , serotonin, enteramine) (Titus and Udenfriend 1954, Erspamer 1955), which is normally present in the central nervous system and may be functionally important It therefore occurred to one of us (M S) that a quantitative examination of the 5-H T. pathway in phenylketonurics might demonstrate a failure of hydroxylation of tryptophan similar to that of phenylalanine This anomaly, if present, might throw some light on the nature of the mental defect hitherto unexplained

Methods

Serum 5-H T—The use of platelet-rich plasma provides a more accurate measure of the amount of 5-H T in blood than does serum (Hardisty and Stacey 1955), but for reasons of convenience it was necessary to use serum for our investigations When blood clots, part of the 5-H T liberated from platelets passes into the red cells (Stacey 1956) and the amount lost in this way depends on the conditions during clotting (Sharman and Sullivan 1956) These must therefore be standardised In the estimations reported here, venous blood was allowed to stand in an incubator at 37°C for an hour without being disturbed and serum was then separated by centrifugation 5-H T was extracted using 95% acetone and assayed on the rat uterus In order to test for the presence of other smooth muscle contracting substances a specific antagonist was applied to the uterus Brom-lysergic acid diethylamide (brom-L S D) in a concentration of 50 ng per ml was found preferable to lysergic acid diethylamide as it caused less spontaneous activity in the uterus

Urinary 5-H I A A excretion was measured by the method of Udenfriend et al (1955) and expressed as mg per g creatinine Creatinine was measured by a Lloyd's reagent adsorption method (Hare 1950) The ferric chloride test (Folling 1934) was used to detect phenylpyruvic acid in the urine and paper chromatographic

Figs 7–9 illustrate the necrosis obtained in three cases in which unscreened radioactive gold rods 0 8 × 5 mm were implanted These results are summarised in table II

Fig 10 shows the necrotic effect of one pellet of radioactive yttrium oxide measuring 1 3 × 3 95 mm, and the result is given in table III

The dose of γ irradiation received at the periphery of the necrotic area, expressed in r, is given in tables I and II In six of the nine cases the dose lay between 68,000 and 93,000 γ r In case 2 (with over 300,000 γ r) the irradiation had acted for only 31 hours, and many of the cells outside the radius of 0 9 mm would probably have died if the patient had lived longer In case 4, on the other hand, the whole of the pituitary in the plane illustrated appears to have received more than 70,000 γ r (derived from two sources) The only surviving cells in this plane are those adjacent to the capsule and surrounding some of the blood-vessels (see below) In case 9 the dose of γ irradiation at the edge of the necrotic area appears to have been more than 190,000r The case has been carefully reconsidered, but no satisfactory explanation has been found for this unusually high value

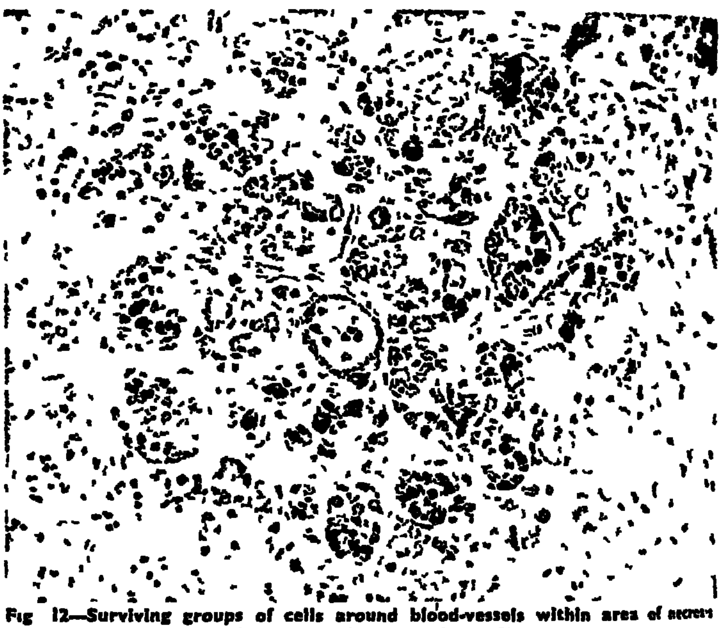

Fig 12—Surviving groups of cells around blood-vessels within area of necrosis (Hæmatoxylin and eosin ×200)

Destruction was incomplete in all fourteen pituitary glands examined One of the four not illustrated contained surviving tissue in spite of the implantation of six grains on three occasions in 7 months, with a total activity of more than 30 mC of radon It is tempting to assume that the small remnants of pituitary found in some of these cases would not be capable of much functional activity This is not necessarily true, for Gomez and Turner (1937) have shown that in animals, in the presence of œstrogens, pituitary remnants as small as 2% of the whole gland can continue to cause considerable breast stimulation There is ample experimental evidence that, after incomplete hypophysectomy, the injection of œstrogens and progesterone will induce a substantial growth reaction in the mammary gland, whereas no mammary response can be induced with these hormones when hypophysectomy has been proved to be total by serial histological examination of the operation site (Folley 1952)

Histology

The histological appearances in the necrotic tissue are those of coagulative necrosis The tissue outlines are preserved, but cytoplasmic staining is entirely eosinophilic, and nuclear staining is lost Pyknotic nuclei are not common and are only seen around the periphery of the necrotic area The nuclei usually undergo karyolysis, but a minority show karyorrhexis A few weeks after the implant, necrotic cells are still clearly defined and the area contains numerous phagocytes, but there is no hyperæmia Later the cell remains are lost and phagocytes disappear, but the reticulin framework persists almost unchanged for a long time Shrinkage of the necrotic area is slight and fibrosis has not developed even after 150 days Granulation tissue has not been seen

On several occasions a narrow rim of surviving cells has been found in close contact with the capsule of the gland, between it and the main area of necrosis (fig 11) The appearance of this rim is similar to that described by Russell (1956) after section of the pituitary stalk and by Wolman (1956) in pituitary necrosis following raised intracranial pressure The distance between the radioactive material and this rim of cells has been found to be less than the distance to the edge of the necrotic area elsewhere (see figs 1, 4, 5, and 8) It follows that these cells possess a greater resistance to radioactivity than do others which have already undergone necrosis from the same dose of irradiation Similar surviving groups of cells have been seen surrounding blood vessels (fig 12) In areas of the pituitary tissue adjacent to necrosis, including those described above, chromophobe and chromophil cells are present The latter may have a granular cytoplasm, and eosinophils sometimes have cytoplasmic vacuoles in addition There is no evidence, however, that one type of cell differs much from another in sensitivity to radioactivity. In fig 13 a section from case 10 has been stained to differentiate eosinophil and basophil cells, both types (together with chromophobe) can be seen in the surviving rim of tissue

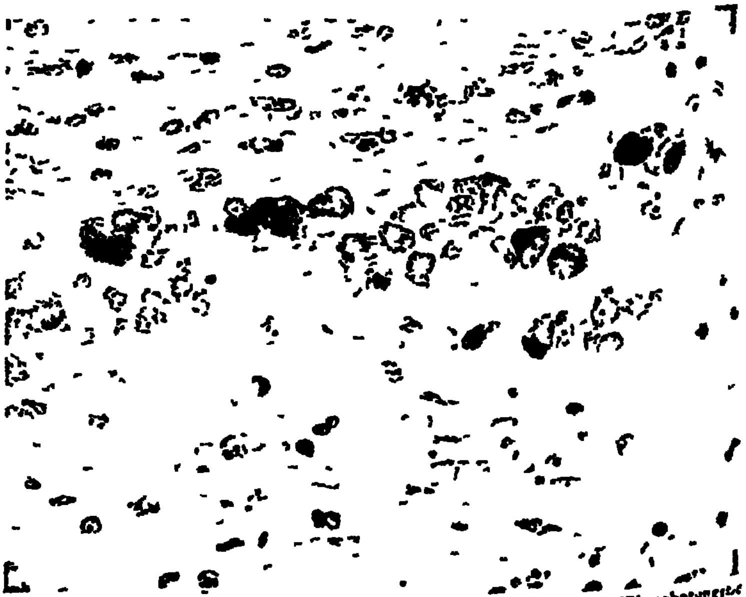

Fig 13—Chromophobe and chromophil cells in surviving rim of tissue (Phosphotungstic acid hæmatoxylin ×450)

It would be of great value if some estimate could be made of the capacity of surviving pituitary tissue to regenerate Mitotic activity has been reported in the pituitary glands of animals after injury and hormone interference, and replacement may be complete if destruction be not too extreme (Cameron 1952) In numerous sections of irradiated pituitary glands, ranging from slight to almost total destruction, and from 31 hours' to 150 days' duration, I have not observed any evidence of mitosis

Possibly the delay between death and fixation of the tissue in these cases has allowed the mitotic process to complete itself before fixation This seems an improbable explanation in view of the fact that mitotic figures can be found in other tissues taken at autopsy It is more likely that the surviving pituitary cells have received sufficient irradiation to delay or to prevent their division

Conclusions

In this series of 14 cases, implants of radioactive gold (^{198}Au) and yttrium (^{90}Y) did not cause complete necrosis of the pituitary

A minimum of about 70,000r of γ irradiation appears to be necessary to cause necrosis in most parts of the pituitary gland

Cells adjacent to the capsule and those around blood-vessels were more resistant to radionecrosis than were those elsewhere

Chromophobe, eosinophil, and basophil cells appeared to be equally susceptible to the necrosing effects of γ and β irradiation

On the basis of the absence of mitotic activity in the apparently undamaged areas of the pituitary, there was no evidence of regeneration

I am grateful to Mr J D Fergusson, director of the Institute of Urology (University of London), Dr L M Franks, Dr R C B Pugh, and Dr C S Treip for access to material, and to Mr E V Willmott and Mr J D Gilbert for technical assistance Dr N R MacKay has given me valuable advice on matters relating to radiotherapy

PHENYLKETONURIA is an inborn error of metabolism characterised by a severe degree of mental deficiency, by the excretion of phenylpyruvic acid in the urine, and by certain bodily features, of which fair hair is the most noticeable

There are several excellent accounts of the condition (Jervis 1937, 1938, Penrose 1946, Cowie 1951a and b), so only a brief survey will be given here Of mental defectives admitted to institutions about 0 5% suffer from the disorder, which is transmitted by a single recessive gene Fundamentally, there is a failure of hydroxylation of phenylalanine to tyrosine in the liver (Jervis 1947, 1953, Udenfriend and Bessman 1953, Armstrong and Shaw 1955) This results in a high plasma concentration of phenylalanine and the presence of many abnormal metabolites in the urine, of which phenylpyruvic acid is the best known (for biochemical review see Dalgliesh 1955) Although the defective hydroxylation of phenylalanine to tyrosine may account for the deficient pigmentation, it has provided no explanation for the other main clinical finding of mental deficiency The intelligence quotient (I Q) in these patients correlates neither with the level of phenylalanine in the blood nor with phenylpyruvic acid excretion in the urine (Borek et al 1950, Jervis 1950) It has been claimed that there is a correlation between the I Q and the amount of phenylpyruvic acid in the plasma, but this correlation is a positive one, plasma levels of phenylpyruvic acid increasing with I Q, and is probably an indication of the state of nutrition (Jervis 1952) Nevertheless various workers have treated affected children with a low-phenylalanine diet for long periods and in general have reported some improvement both in intelligence and in physical condition (Bickel et al 1953, Armstrong and Tyler 1955, Woolf et al 1955) Armstrong and Tyler (1955) conclude that " it seems probable that unknown and possibly complex factors other than the known defect in phenylalanine oxidation operate in conjunction with it and contribute to the mental defect ".

Recently, Armstrong and Robinson (1954a and b) have offered evidence of abnormal indole metabolism in phenylketonuria, demonstrating the presence of indolelactic acid (I L A) in the urine of affected patients They also claimed, from paper chromatographic studies, that there was a decreased urinary excretion of 5-hydroxyindoleacetic acid (5-H I A A) in some of their patients Their findings were confirmed by Ferrari and his colleagues (1955)

5-H I A A is known to be a metabolite of 5-hydroxytryptamine (5-H T, serotonin, enteramine) (Titus and Udenfriend 1954, Erspamer 1955), which is normally present in the central nervous system and may be functionally important It therefore occurred to one of us (M S) that a quantitative examination of the 5-H T pathway in phenylketonurics might demonstrate a failure of hydroxylation of tryptophan similar to that of phenylalanine This anomaly, if present, might throw some light on the nature of the mental defect hitherto unexplained

Methods

Serum 5 H T—The use of platelet-rich plasma provides a more accurate measure of the amount of 5 H T in blood than does serum (Hardisty and Stacey 1955), but for reasons of convenience it was necessary to use serum for our investigations When blood clots, part of the 5-H T liberated from platelets passes into the red cells (Stacey 1956) and the amount lost in this way depends on the conditions during clotting (Sharman and Sullivan 1956) These must therefore be standardised In the estimations reported here, venous blood was allowed to stand in an incubator at 37°C for an hour without being disturbed and serum was then separated by centrifugation 5-H T was extracted using 95% acetone and assayed on the rat uterus In order to test for the presence of other smooth muscle contracting substances a specific antagonist was applied to the uterus Brom lysergic acid diethylamide (brom L S.D) in a concentration of 50 ng per ml was found preferable to lysergic acid diethylamide as it caused less spontaneous activity in the uterus

Urinary 5-H.I A.A excretion was measured by the method of Udenfriend et al (1955) and expressed as mg per g creatinine Creatinine was measured by a Lloyd's reagent adsorption method (Hare 1950) The ferric-chloride test (Folling 1934) was used to detect phenylpyruvic acid in the urine and paper chromatographic studies of urinary indoles were carried out by the method of Jepson (1955).

The intelligence tests used (kindly carried out by Mrs. L. Mundy, M.SC., and Miss M. Woodward, PH.D.) were the Stanford Binet (Terman-Merrill revision), the Merrill Palmer, and the Vineland Social Maturity scale.

Results

Four groups of children were investigated.

Group 1.—Twelve normal children, 3–12 years of age, living at home. We thought it unjustifiable to take venous blood samples from them, so that in this group only 5-H.I.A.A. excretion has been determined.

Group 2.—Fifteen children admitted to hospital from a tonsillectomy waiting list and awaiting operation.

Group 3.—Ten phenylketonurics (table I (*a*)), all of whom had a positive ferric chloride test and had chromatographic evidence of P.P.A. in the urine.

Group 4.—Nine mentally defective children, without phenylketonuria, living in the same hospital as the phenylketonurics (table I (*b*)).

All the mentally defective children had been in hospital for at least 12 months and were in a good state of health and nutrition.

The means of the urine and blood estimations are summarised in table II together with results from normal adults. There is a conspicuous difference between the means of the different groups. The phenylketonurics show significantly lower values than all others both with respect to serum 5-H.T. ($P < 0.01$) and urine 5-H.I.A.A. ($P < 0.02$). The difference between the serum 5-H.T. of the phenylketonurics and the other mental defectives is particularly striking; only one phenylketonuric had a serum-5-H.T. above 100 ng. per ml. and only one of the other mental defectives was below this. Similarly, 5-H.I.A.A. levels overlapped in only two patients.

One cause of a low level of 5-H.T. in blood and serum is thrombocytopenia (Bigelow 1953, Hardisty and Stacey 1957). There is no evidence that this is common in phenylketonuria; platelet counts in patients no. 13 and 18 were within normal limits (378,000 and 500,000 per c.mm. respectively).

No correlation was found between the I.Q. of patients with phenylketonuria and their serum-5-H.T. and 5-H.I.A.A. excretion.

The 5-H.I.A.A. excretion of children awaiting tonsillectomy was considerably higher than that of normal children at home. This has not yet been further investigated.

Some of the non-phenylketonuric mentally defective children had surprisingly high serum 5-H.T. When these were repeated after an interval of 6 months substantially similar results were found in each case. In some of the sera in both groups of mentally defective children traces of another smooth-muscle-contracting substance, not antagonised by brom-L.S.D., was found. The amount of this other substance was in all cases small and cannot be the sole cause for high 5-H.T. figures as in some of the sera with high values (e.g., no. 14) all activity was antagonised by brom-L.S.D.

TABLE II—SUMMARISING MEAN VALUES AND STANDARD ERRORS OF THE MEAN (S.E.M.) OF SERUM 5-H.T. AND URINE 5-H.I.A.A. IN PHENYLKETONURIC AND CONTROL GROUPS

Group	—	Serum 5-H.T. Mean ± S.E.M. (ng. per ml.)	Urine 5-H.I.A.A. Mean ± S.E.M. (mg. per g. creatinine)
I	Normal children (12 subjects)		6·6 ± [illegible]
II	Children awaiting tonsillectomy (15 cases)	124 ± 14	11·0 ± 1·3
III	Phenylketonurics * (9 cases)	57 ± 11	2·9 ± 0·[illegible]
IV	Other mental defectives (9 cases)	270 ± 51	4·9 ± 0·[illegible]
	Normal adults	99 ± 16	4·4 ± 0·5

* The phenylketonuric group includes two patients in whom either 5-H.T. or 5-H.I.A.A. estimations alone were performed.

Discussion

Tryptophan has been demonstrated by isotopic studies with ^{14}C-labelled compounds to be the precursor of 5-H.T. (Udenfriend et al. 1956a). It is presumably hydroxylated to 5-hydroxytryptophan (5-H.T.P.) (Smith et al. 1957), decarboxylated to 5-H.T. (Clark et al. 1954), and metabolised by monoamine oxidase to be excreted in the urine as 5-H.I.A.A. (Blaschko 1952, Sjoerdsma et al. 1955). The finding of a low serum-5-H.T. and a diminished 5-H.I.A.A. excretion in patients with phenylketonuria is compatible with the view that there is in these patients a disturbance in tryptophan metabolism which results in a diminished production of 5-H.T. During the past few years evidence has accumulated that 5-H.T. plays an important part in the central nervous system. It has been shown, for example, that the ability to synthesise 5-H.T. from its immediate precursor, 5-H.T.P., and to store it occurs in particular regions of the grey matter (Amin et al. 1954, Gaddum and Giarman 1956); further, Feldberg and Sherwood (1954) in animal experiments, have described characteristic changes in behaviour following the injection of 5-H.T. into the cerebral ventricles. In view of this it seems possible that impaired 5-H.T. synthesis may contribute to the causation of mental deficiency in patients with phenylketonuria.

Two lines for further investigation suggest themselves. The administration of 5-H.T. is unlikely to benefit these patients because it is rapidly destroyed in the circulation and because it does not easily pass the blood-brain barrier (Bogdanski et al. 1956). If phenylketonurics have an impaired capacity to hydroxylate tryptophan, as seems likely, the administration of 5-H.T.P. might overcome this deficiency. Moreover, 5-H.T.P. readily passes the blood-brain barrier and in animal experiments has been shown to raise brain 5-H.T. concentration (Udenfriend et al. 1956b).

In the second place it has been observed that the mental condition of some patients with phenylketonuria improves on a low-phenylalanine diet (Bickel et al. 1953, Armstrong and Tyler 1955, Woolf et al. 1955). Could such a diet improve 5-H.T. synthesis? Any answer must at the moment be guesswork; but if phenylalanine competes with tryptophan for hydroxylation, a reduction in blood-phenylalanine would favour hydroxylation of tryptophan and result in a raised serum-5-H.T. level and raised 5-H.I.A.A. excretion. We are pursuing both these lines of investigation.

Summary

The levels of 5-hydroxytryptamine in the serum and of 5 hydroxyindoleacetic acid in the urine were assayed in children with phenylketonuria and in controls Abnormally low levels of both were found in the phenylketonuric group The relation of these findings to the mental deficiency in phenylketonuria is discussed

We are indebted to Dr L T Hilliard and Dr B H Kirman of the Fountain Hospital, for the facilities which they gave us We are grateful to Dr D N Baron for his constructive criticism We should like to thank Miss Joan Wise, B SC, for technical assistance and the Royal Free Hospital Endowment Fund for defraying her salary and for apparatus Messrs Roche Products kindly supplied 5 hydroxytryptamine

DEFECTIVE ORGANIC BINDING OF IODINE BY THE THYROID IN HASHIMOTO'S THYROIDITIS

M E MORGANS
M B Lond, M R C P
W R TROTTER
D M Oxfd, M R C P
From the Medical Unit University College Hospital Medical School, London

IN normal circumstances labelled iodide is rapidly bound by the thyroid gland and incorporated in organic compounds If the formation of hormone is interfered with, as it is when a person is given an anti thyroid drug of the thiouracil series, much of the labelled material remains concentrated within the thyroid in the form of inorganic iodide Stanley and Astwood (1948) showed that this state of affairs could be easily demonstrated by administering a large dose of thiocyanate When the person was under the influence of an anti-thyroid drug, thiocyanate caused most of the labelled iodine to be discharged from the thyroid into the general circulation In untreated subjects labelled iodine was not discharged by thiocyanate, but no more was taken up

A similar technique has been used to show that the action of other drugs, such as *p*-aminosalicylic acid (Edwards et al 1954) and phenylbutazone (Morgans and Trotter 1955), on the thyroid gland is similar to that of thiouracil In these studies the place of thiocyanate was taken by perchlorate, which has a similar though more potent effect (Stanbury and Wyngaarden 1952)

It is possible that anti thyroid substances known to be present in some foodstuffs may be a contributory cause of simple goitre (Astwood 1949, Clements and Wishart 1956) If so, it might be expected that the technique of Stanley and Astwood (1948) would reveal defective organic binding of iodine in some patients with this condition

During the past few years we have investigated some cases of simple goitre in this way With a single exception (see below) these cases of simple goitre have reacted in an entirely normal fashion, perchlorate has failed to discharge any of the radio-iodine taken up by the thyroid, and hence it can be assumed that organic binding of iodine was proceeding normally But, when the investigation was extended to include cases of Hashimoto's thyroiditis (lymphadenoid goitre), it was found that the administration of perchlorate was often followed by a considerable loss of radio-iodine from the thyroid

Clinical Material

12 patients believed to have Hashimoto's thyroiditis were studied 6 of them had undergone thyroidectomy, and histological sections showed the typical appearances of Hashimoto's thyroiditis 4 of the remainder had positive serum-flocculation tests and raised serum-gamma globulin levels (Fromm et al 1953, Skillern et al 1956, Luxton and Cooke 1956), and in 2 of these the diagnosis was further confirmed by a precipitin reaction against thyroglobulin (Roitt et al 1956) Of the remaining 2 patients one had clear signs of myxœdema with a small firm diffuse goitre, the other presented with a fairly large firm diffuse goitre, which disappeared after X ray therapy with the simultaneous development of symptoms of myxœdema Serum has not yet been obtained from these 2 cases for confirmatory tests

The 26 cases classed as simple goitre included both those with diffuse and those with nodular glands, thyroid function being normal in all cases

Method

The patients came for their tests at least five hours after the last meal 20-40 µC doses of radio iodine ^{131}I were given by mouth, and counts were made simultaneously over the thyroid and thigh regions with a standard Geiger counter at fifty and sixty minutes after the dose Immediately after the sixty-minute count the patients drank a solution of potassium perchlorate containing either 200 mg or 400 mg with 25 or 50 ml of water respectively The counting-rate opposite the neck and thigh was measured at ten, twenty, thirty, and forty minutes after the administration of perchlorate

In calculating the results half the thigh count was subtracted from the neck count, because previous experience with subjects in whom the thyroid was absent or temporarily out of action showed that, with the particular geometrical arrangement of counters used by us, the extrathyroid radioactivity in the neck amounts to about half the thigh count This gives an approximate estimate of the radioactivity in the thyroid gland The values thus calculated for thyroid radioactivity at ten, twenty, thirty, and forty minutes were then expressed as a percentage of the thyroid radioactivity present immediately before the perchlorate was given

EFFECT OF PERCHLORATE ON THYROID RADIOACTIVITY

Diagnosis	No of cases	Dose of perchlorate (mg)	Thyroid count as percentage of initial value (mean and S E)			
			Interval after perchlorate (min)			
			10	20	30	40
Healthy	7	200	116(±13)	117(±12)	114(±7)	113(±2)
Thyrotoxicosis	5	200	116(±3)	119(±6)	120(±8)	115(±4)
Simple goitre	19	200	124(±4)	126(±3)	121(±4)	128(±5)
Hashimoto's thyroiditis	5	200	99(±1)	85(±7)	82(±10)	71(±13)
Simple goitre	7	400	111(±8)	111(±8)	109(±7)	114(±7)
Hashimoto's thyroiditis	7	400	80(±7)	65(±15)	57(±10)	43(±9)

The thyroid count has been expressed as a percentage of the thyroid count immediately before perchlorate was given—i e the count at 1 hour after the tracer dose of radio iodine

Results

In the earlier cases in this series the dose of potassium perchlorate was 200 mg We later suspected that this dose might not be sufficient to give the maximal response, and therefore we doubled it Although this suspicion was never proved, it is worth noting that the mean values of the relative thyroid count from the cases of simple goitre were lower in the group given 400 mg than in the group given 200 mg at all time intervals after the administration of perchlorate (see table) The same is true of the cases of Hashimoto's thyroiditis when they are subdivided according to the dose of perchlorate. In neither case, however, is there a significant difference between the mean values obtained with the two doses There would therefore be formal justification for assuming that the dose of perchlorate given was immaterial and for using the combined results from both doses in a comparison of the responses of patients with simple goitre and of patients with Hashimoto's thyroiditis It is, however, possible that the higher dose was really more effective, but that the significance of the effect was obscured by the high variance and small numbers in the groups In view of this possibility we thought that it would be prudent to consider the results with the two doses separately

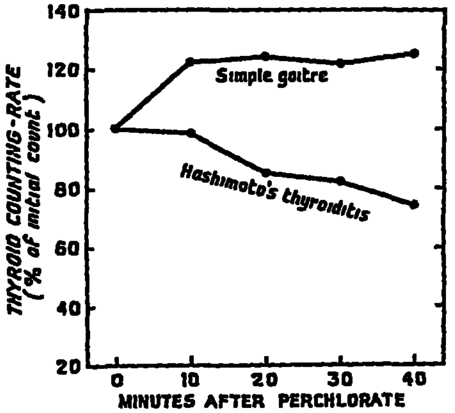

Fig 1—Mean values of thyroid counting rate at intervals after administration of potassium perchlorate 200 mg

Figs 1 and 2 and the table show that in normal subjects and in patients with simple goitre or thyrotoxicosis the thyroid counting-rate tends to rise slightly during the first ten minutes and then remains level The initial rise represents the continued fixation of radio iodine before the perchlorate reaches the thyroid in adequate quantities Thereafter, the iodide concentrating mechanism being out of action, the thyroid can no longer bind appreciable quantities of radio iodine, so the thyroid count remains steady The mean values for the patients with goitre or thyrotoxicosis did not differ significantly from those of the normal subjects at any time-interval

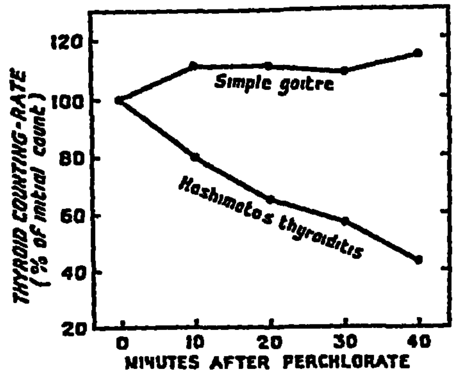

Fig 2—As fig 1 after 400 mg of potassium perchlorate

The relative thyroid counting-rate at forty minutes after perchlorate can conveniently be used as a rough measure of the defect in organic binding of iodine These values are shown in figs 3 and 4 as histograms for each of the groups studied With only 1 exception, all the subjects with normal, goitrous, or thyrotoxic thyroids, who were given 200 mg of perchlorate, retained 90% or more of the radio iodine in their glands There was therefore no detectable quantity of free radio active iodide present in the thyroid and organic binding *is assumed to be complete*

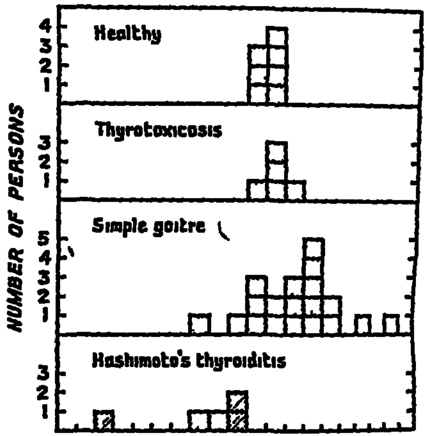

Fig 3—Frequency distribution of thyroid counting rate at 40 minutes after 200 mg of potassium perchlorate hatched squares indicate cases of histologically proved Hashimoto's thyroiditis

This conclusion does not apply, however, to our patient with simple goitre, who retained only 78% of the radio iodine in her thyroid She had what appeared to be an ordinary nodular goitre, with typical histological appearances and no excess of lymphoid tissue The perchlorate test was repeated after the operation, with almost identical results The patient is, however remarkable in that her mother and all her four siblings also have goitres Of these, only one sister has so far been investigated, her response to perchlorate was quite normal

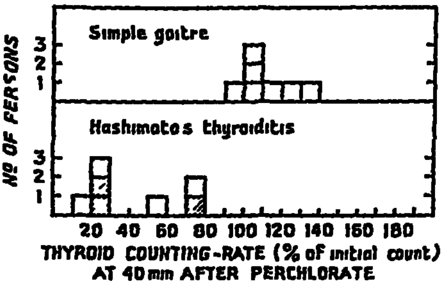

Fig 4—As fig 3 after 400 mg of potassium perchlorate

The 5 patients with Hashimoto's thyroiditis who had been given 200 mg of perchlorate all retained less than 91% of the radio iodine initially present in the thyroid *The mean value for the percentage retained at forty minutes is significantly different from the mean value for the groups* with normal goitrous, or thyrotoxic thyroids (P<0·005)

When 400 mg of perchlorate was given, all the patients *with simple goitre retained 90% or more of the* radio iodine initially present in the thyroid In contrast all the 7 with Hashimoto's thyroiditis retained less than 80% (fig 4) As we have no proof that 400 mg of per chlorate was more effective than 200 mg, it may well be that this sharp differentiation between the two groups was fortuitous, and that overlap would become apparent if more cases were studied

As there was necessarily some doubt about the diagnosis in those cases in which thyroidectomy was not performed, it is necessary to consider the histologically proven cases of Hashimoto's thyroiditis separately The mean relative thyroid counting-rate at forty minutes for this group differs significantly from the mean value for the combined cases of simple goitre (P <0 001)

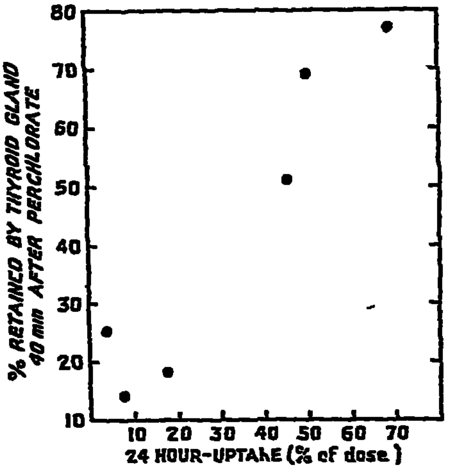

Fig 5—Relation between 24-hour uptake of radio-iodine by thyroid gland and proportion retained in thyroid gland 40 min after perchlorate in 6 cases of Hashimoto's thyroiditis in which both tests were made

Discussion

When perchlorate was given to patients with Hashimoto's thyroiditis, labelled iodine tended to leave the thyroid This is taken to mean that the portion discharged by perchlorate was in the form of inorganic iodide Hence organic binding of iodine was still incomplete at one hour after a tracer dose of radio-iodine There was nothing to suggest that these patients had been consuming anti-thyroid substances, or iodides, in their food or as drugs It seems equally unlikely that they had a congenital enzyme defect, such as Stanbury and Hedge (1950) postulated for their goitrous cretins, since Hashimoto's thyroiditis usually starts in middle age

A possible explanation of the defective binding of iodine is provided by recent evidence (Roitt et al 1956, Rose and Witebsky 1956) which suggests that Hashimoto's thyroiditis is the result of an auto-immune response to thyroglobulin This interesting hypothesis will require further confirmation, and there is at present no indication of the anatomical site at which the presumed antigen-antibody reaction occurs A plausible guess might be that thyroglobulin is formed within the epithelial cells of the thyroid, and that the antibody might unite with it soon after its formation If thyroglobulin were incompletely iodinated at this stage, it is possible to conceive that the antibody might actually cover up some of the available tyrosine radicles and so prevent the first stage of hormone formation This would result in defective organic binding of iodine and so allow inorganic iodide to accumulate in the thyroid This suggestion is put forward as a possible way of bringing together our observations and recent immunological work, but, as it is based on no more than guesswork, its only function is to serve as a pointer to further investigations

The existence of a partial block to iodination helps to explain the very varied results obtained in studies of twenty four-hour uptake of radio iodine in patients with Hashimoto's thyroiditis These may be low, normal, or high The histological evidence suggests that the thyroid in this condition is under strong stimulation by the pituitary The combination of various degrees of iodination defect, with attempted compensation by the pituitary, would go some way to explain these diverse results The degree of iodination defect appears to be correlated with the twenty-four-hour uptake of radio-iodine (fig 5)

We have found the perchlorate test of some practical use in diagnosis, although it will not necessarily differentiate all cases of Hashimoto's thyroiditis from other types of goitre, and there may be exceptional cases of simple goitre which do show some discharge after perchlorate Our experience with the precipitin test of Roitt et al (1956) is that it is usually but not invariably positive in Hashimoto's thyroiditis The flocculation tests are also useful but less specific We feel that a combination of all three tests—perchlorate, precipitin, and flocculation—will give a high degree of diagnostic accuracy and thus obviate the need for biopsy in most cases

Summary

When potassium perchlorate is given to normal subjects one hour after a tracer dose of radio-iodine, the thyroid counting-rate rises slightly and then remains constant This is taken to mean that, by this time, almost all the labelled iodine in the thyroid gland is organically bound

25 patients with simple goitre reacted in the same way

1 patient with simple goitre and an exceptionally strong family history of goitre showed some discharge of thyroid radioactivity after the administration of perchlorate

In 12 cases of Hashimoto's thyroiditis there was a significant tendency for thyroid radioactivity to be discharged after the administration of perchlorate These observations are taken to mean that an appreciable proportion of the administered radio-iodine was still present in the thyroid in the form of iodide at the time the perchlorate was given This is presumptive evidence of a partial defect in the organic binding of iodine by the thyroid in Hashimoto's thyroiditis

One of us (W R T) is in receipt of a grant from the Sir Halley Stewart Trust

' In a competitive society like ours, almost every formative influence to which we are subjected from the cradle to the grave conspires to persuade us to seek worldly success and to avoid failure, to be proud of achievement and to be ashamed of defeat or weakness But these utilitarian standards by which we are being measured are sub personal standards The only emotions they encourage in us are variations on the themes of fear and ambition, both of which make it almost impossible for us either to give or to accept the inner freedom and self-possession that go with emotional maturity The instability of modern marriage is not an isolated phenomenon that can be explained and remedied by attention to local conditions or individual cases It is one of many social disorders stemming from a single cause namely, the determination of modern man to make material prosperity the chief aim of his life I see no hope of man being able to liberate himself from this enslavement to the economic machinery he has invented until he sees clearly, and with conviction derived from his own personal experience, that the price he is paying for his aim is a deterioration of his spiritual integrity, emotional maturity and happiness.' —PETER FLETCHER in *Marriage and the Community* (published by the British Social Biology Council, Tavistock House South, Tavistock Square, London, W C 1, at *1s 6d*)

A METHOD FOR EVALUATION OF HYPNOTIC DRUGS

BERNARD ISAACS
M B Glasg, F R F P S
CIBA RESEARCH FELLOW IN CLINICAL PHARMACOLOGY, DEPARTMENT OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY OF GLASGOW

IN comparing hypnotic agents in man two major difficulties are encountered. (1) standardisation of the environmental conditions, and (2) measurement of the depth of sleep induced In the present study the first difficulty was overcome by using as subjects normal *medical students rather than hospital patients, and by* conducting the tests in their own homes The depth of sleep was measured by a new method which is simple and objective

Principle of the Method

Just before retiring to bed, the subject swallowed special capsules of the drug under test, emptied his bladder, and drank a large volume of water Because of this "water load," much urine was secreted during sleep, and the subject was sooner or later roused by the discomfort of his full bladder Rising to micturate, he noted the duration of sleep and the volume of urine passed When, because of the action of a hypnotic drug, sleep was deeper than usual, waking was delayed and a larger volume of urine was voided on waking Both the duration of sleep and the volume of urine passed on waking were taken into account in assessing the average depth of sleep during the night This was represented by the equation

$$D = \log t \times \log v$$

where D was the mean depth of sleep, t the time in minutes from retiring to first waking, and v the volume of urine in millilitres passed on first waking The use of this expression is discussed below Comparison of the values for log t × log v after taking various hypnotic drugs gave a measure of their relative hypnotic potency

Experimental Details

Design of the Experiment

The subjects were healthy male medical students Each man volunteered to take part in four tests at intervals of a week He was asked to perform a test on the same night each week after an evening spent at home In each test unknown capsules were taken on retiring, and at the same time a water load was drunk The capsules which were tasteless and indistinguishable in appearance, comprised

(i) Inert capsules
(ii) and (iii) A standard with which the new drug was to be compared—e g, pentobarbitone in two doses
(iv) The drug to be evaluated

The method of interpreting the data is considered here, the findings with glutethimide are presented in the accompanying article

Measurement of the Depth of Sleep

A method of representing the depth of sleep was sought which would remain uninfluenced by unavoidable differences in the rate of urine flow in different tests To test the suitability of the parameter D = log t × log v, 91 students drank a water load and *took inert capsules on retiring to bed* They recorded the duration of sleep and the volume of urine passed on waking The value of log t × log v from each test was plotted against the corresponding value of t (fig 1) and of v (fig 2) When t was less than 200, log t × log v was low but increased as t increased When t was greater than 200, log t × log v tended to increase only slightly with v, but the two measures were nearly independent of one another

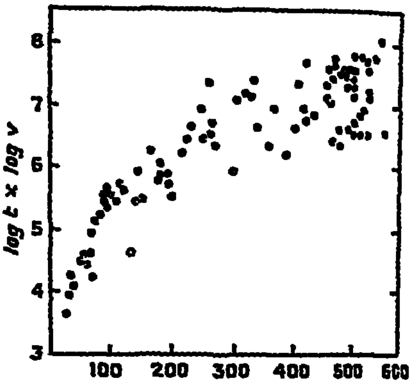

Fig 1—Values of log t × log v plotted against the corresponding sleeping time

The interpretation of these results is that, in general, high waking-volumes of urine were associated with short sleeping-times, and vice versa The value of log t × log v gave a reasonable estimate of the mean depth of sleep which was independent of the rate of urine flow, provided that sleep lasted for more than three hours

When sleep was short it was usually light, and low values of *log t × log v were to be expected with low* values of t But this expression gave unduly low values when the rate of urine flow was high

Suppose, for example, that the subject slept for sixty minutes and that the waking volume of urine was 500 ml The high rate of urine flow represents a strong waking stimulus and indicates moderately deep sleep We have

$$t = 60 \qquad \log t = 1.78$$
$$v = 500 \qquad \log v = 2.70$$
$$\log t \times \log v = 4.81$$

which is an erroneously low estimate of the depth of sleep

Such high rates of urine flow were not aimed at in this test, and a correction was required when they occurred It was decided to reject from the experiment records in which the waking stimulus was "excessive," defined as one which resulted in the subjects' waking less than sixty minutes after retiring, when the mean rate of urine flow exceeded 5 ml per minute Such records were unsuitable also because one hour might not be sufficient time for a hypnotic drug, taken on retiring, to exert its full effect

Difficulties might also be introduced from an unduly low rate of urine-flow

Suppose that a subject slept for eight hours and passed 400 ml of urine on waking We have

$$t = 480 \qquad \log t = 2.68$$
$$v = 400 \qquad \log v = 2.60$$
$$\log t \times \log v = 6.97$$

This value is higher than the average for log t × log v, and such a result is consistent with lighter than average sleep But the same figures might have been obtained after deep *sleep, since the subject would waken after eight hours*

As the effect of a low rate of urine-flow is to obscure *differences between light and deep sleep, it was desirable*

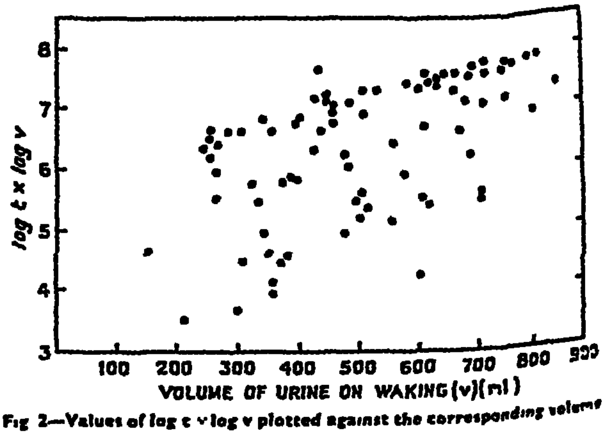

Fig 2—Values of log t × log v plotted against the corresponding volume of urine on waking

to exclude from the experiment records in which the stimulus was "inadequate," defined as one which resulted in sleep lasting for more than seven hours, and in which the subject passed less than 400 ml of urine on waking These figures were based on an experiment in which 20 students recorded the duration of sleep and the volume of urine on waking after an ordinary night's sleep when no water load had been taken In 18 students, sleep lasted for more than seven hours, and in 15 of these the volume of urine on waking was less than 400 ml

Provided that unsuitable records were rejected, it was considered that log t × log v gave a reasonable estimate of the depth of sleep

Choice of a Suitable Water Load

Preliminary studies suggested that 500 ml taken immediately before retiring was a suitable water load This volume was used at first in the main experiment, but almost a third of all records had to be rejected because the waking stimulus was "inadequate" as defined above (table I) During the remainder of the experiment a larger water load was used—500 ml an hour before bedtime and another 500 ml at bedtime This proved more suitable, but several records had to be rejected because the waking stimulus was "excessive" as defined above

It was necessary to determine whether altering the water load during the experiment affected the values of log t × log v Table II shows that the values obtained after hypnotic drugs were the same with both water loads After inert tablets, the values were lower with the high than they were with the low water loads This was because, with the higher water load, the subject often awoke in the second hour after retiring, when values of log t × log v were low

TABLE I—INFLUENCE OF THE MAGNITUDE OF THE WATER LOAD ON THE RATE OF URINE FLOW

(For definitions of "inadequate" and "excessive" see text)

Water load	Adequate	Inadequate	Excessive
500 ml once	85	49	5
500 ml twice	133	10	17

Because of the cross over design of the experiment, changing the water load during it did not invalidate comparisons between drugs In future experiments, however, other water loads should be tried It seems unwise to give water an hour before retiring

Effect of Drugs on Water Diuresis

To make sure that the drugs tested did not themselves influence water diuresis, an experiment was undertaken

12 convalescent hospital patients each drank 500 ml of water and swallowed the active or placebo capsules used in this study The course of the diuresis was followed at half hour intervals for three hours No alteration in the pattern of diuresis attributable to the drugs was detected The results however varied widely, both between subjects and between drugs To be certain that the hypnotic drugs had no antidiuretic effect, these studies would have to be made on a much larger scale

Previously glutethimide had been shown to have no such effect (Gross 1956), and pentobarbitone has not been shown to affect diuresis except in large doses in dogs (de Bodo and Prescott 1945)

Statistical Considerations

TABLE II—INFLUENCE OF THE WATER LOAD ON THE MEAN VALUE OF LOG t × LOG v AFTER THE VARIOUS DRUGS

(Records classed as "inadequate" or "excessive" are not included)

Drug	Water load	No of experiments	log t × log v	
			Mean value	Standard error
Control	500 ml once 500 ml twice	31 35	6 69 6 26	0 15 0 16
Pentobarbitone gr 1½	500 ml once 500 ml twice	23 42	7 04 7 06	0 18 0 10
Pentobarbitone gr 3	500 ml once	20	7 34	0 18
Glutethimide 500 mg	500 mg once 500 ml twice	25 45	6 88 6 96	0 18 0 14

It was decided to obtain four values of log t × log v for each subject in the experiment, one value corresponding to each of the four sets of capsules If for any reason one record from any subject had to be rejected, then the other results from that subject could not be used *in the analysis* Our experience suggests that valid results could probably be obtained if 20 subjects entered the experiment

The results were examined by a two-way analysis of variance This showed that variation between subjects contributed more to the total variance than did variation between drugs Values could be obtained for the probability of the significance of observed differences between the active drugs and the placebo, and between the different active drugs

Discussion

This method of evaluating hypnotic drugs assumes that they increase the resistance of the sleeping brain to arousal stimuli from the filling bladder No assumption need be made about the site or mechanism *of such an* action The expressions "mean depth of sleep" and "resistance to waking impulses" are used because they are convenient in the context of this experiment It is not claimed that those terms have true physiological meaning

Several other methods have been used for the quantitative evaluation of hypnotic agents in man Many of these depend in part on the patient's own report of the duration and quality of sleep (Lasagna 1954, Foltz et al 1955, Rushbrooke et al 1956) or on the reports of nurses or technicians (Lasagna 1954) In another method the doses which produced comparable degrees of depression of the central nervous system (Foltz et al 1955) were determined for different hypnotic drugs Electro encephalographic studies of sleep after hypnotic drugs have also been made (Ladwig 1955) but these are of limited application No one method used alone can give a satisfactory objective measurement of the hypnotic properties of drugs

The following advantages are claimed for the method proposed here

1 Normal healthy subjects are used

2 The tests are performed in the subjects' own homes

3 Repeated tests with different drugs or different doses are performed on the same subjects, and a cross over experimental design can be used in which the subjects act as their own controls

4 No elaborate apparatus and no observers are needed

5 The method of measuring the depth of sleep is objective and free from bias, and observer error is slight

6 Only physiological stimuli are employed

7 *Statistically* valid results can be obtained with relatively few subjects

The method has the following disadvantages

1 It is not used in patients who actually require hypnotic drugs

2 It gives no information about the time of onset of the drug's action or its duration of action

3 It gives no information about side effects or after-effects

4 It can provide only comparative information against drugs of known potency

5 It assumes that the drugs tested have no action on the bladder or on water diuresis

Some of the disadvantages are common to other methods of evaluating hypnotic drugs

This method can be applied in the evaluation of new hypnotic drugs, and in measuring the hypnotic side-effects of drugs such as anti-histamines, provided that an effect of the drug on water diuresis or on the bladder can be excluded

Summary

A method is described for the evaluation of hypnotic drugs in man The method depends on determining the resistance of the sleeping subject to waking impulses from the filling bladder Before retiring, and at the time of taking the drug under test, the subject drinks a large volume of water On waking he records the duration of sleep (t minutes) and the volume of urine passed on waking (v ml.) It is shown that the expression log t × log v can then be used as an empirical measure of the mean depth of sleep, and thus of the relative potency of hypnotic drugs

HYPNOTIC EFFECT OF GLUTETHIMIDE IN NORMAL HUMAN SUBJECTS

BERNARD ISAACS
M.B Glasg, F R F P S
CIBA RESEARCH FELLOW IN CLINICAL PHARMACOLOGY, DEPARTMENT OF MATERIA MEDICA AND THERAPEUTICS, UNIVERSITY OF GLASGOW

GLUTETHIMIDE (α-phenyl α-ethylglutarimide, 'Doriden') is a new non-barbiturate hypnotic (Gross et al 1955) Experimental and clinical studies suggest that it may be a useful substitute for barbiturates (Ladwig 1955, Müller and Rohrer 1955, Rushbrooke et al 1956). I record here an attempt to measure its action in normal people

Material and Methods

The majority of a class of medical students volunteered for the trial The women took part in a subjective study designed to give information mainly on side effects The men (average age 21) took part in an objective study designed to give quantitative information on the hypnotic potency of the drugs tested Each student undertook, in his own home, a series of four tests on himself, as described in the previous article For each test he received a pair of capsules which, he was told, might or might not contain a hypnotic drug The capsules were tasteless and indistinguishable in appearance, and contained one of the following (the doses are the total for two capsules)

1	Lactose	500 mg
2	Pentobarbitone	100 mg (gr 1½)
3	Pentobarbitone	200 mg (gr 3)
4	Glutethimide	500 mg

All students were to receive the four different sets of capsules, one kind each week *The order in which they* were given differed at random for each student, all 24 possible sequences being used The women were given the following questionary to be completed on the day after the test

1 Did you sleep (A) the same as usual ?
(B) more soundly than usual ?
(C) less soundly than usual ?

2 Did you fall asleep (A) less easily than usual ?
(B) as usual ?
(C) more easily than usual ?

TABLE I—ANSWERS TO THE QUESTIONARY

Question	Answer	Numbers providing each answer after taking			
		Control	Pentobarbitone gr 1½	Pentobarbitone gr 3	Glutethimide 500 mg
1	A	24	22	4	21
	B	2	8	6	5
	C	2	0	0	0
2	A	2	1	0	3
	B	26	27	8	23
	C	0	2	2	3
3	A	1	7	3	3
	B	3	2	0	0
	C	24	21	7	26
4	A	25	18	3	24
	B	3	1	1	0
	C	0	11	6	5
5	A	0	8	9	9
	B	2	0	0	0
	C	26	22	1	20

3 Did you waken during the night (A) less than usual ?
(B) more than usual ?
(C) as usual ?

4 Did you waken in the morning (A) as usual ?
(B) with less difficulty than usual ?
(C) with more difficulty than usual ?

5 On waking did you feel (A) unusually tired ?
(B) unusually fresh ?
(C) as usual ?

6 During the day did you notice any unusual symptoms and if so what were they ?

The male students were issued with a record form and a plastic cylinder for urine collection

In the subjective study, the women took their capsules on retiring to bed, but did not alter their usual bedtime habit Next morning they answered questions 1-4 of the questionary by ringing A, B, or C, questions 5 and 6 were answered in the evening 34 students entered the experiment, but a few withdrew in the course of it

TABLE II—SIDE EFFECTS

Symptom	Number complaining after taking			
	Control	Pentobarbitone gr 1½	Pentobarbitone gr 3	Glutethimide 500 mg
Unusually tired, sleepy	0	5	5	6
Dizzy, light headed	0	5	7	3
Ataxia slurred speech	0	2	8	[illegible]
Headache	0	1	1	0
Nausea	0	0	3	0
Lack of concentration	0	0	1	2
Argumentative	0	0	1	0
Confused as though drunk	0	0	3	4
Irritable	0	0	2	0
Apathetic	0	0	1	1

All the results obtained were used in the analysis but the numbers in the different drug groups differ slightly

In the objective study, using male students, the method described in the accompanying paper was adopted It measures the ability of the drug to maintain sleep despite the waking stimulus of a full bladder

Results

The studies were run simultaneously When the results for the first week came to hand, it was apparent that in the majority of students pentobarbitone gr 3 had caused drowsiness and mental confusion on the day after the test This dose was therefore withdrawn from the trial In all experiments with male students with the dose of pentobarbitone the water load was therefore 500 ml only

Subjective Trial (Women)

The answers to the questionary are presented in tables I and II and the statistical analysis in table III After taking placebo capsules almost all students described their sleep as "usual," and none complained of after-effects This apparent lack of suggestibility contrasts with the findings of other studies on the subjective effects of drugs on "sophisticated" observers, such as medical students (Glaser 1953, 1954, Glaser and Whittow 1954)

Questions 1–3 provide little information about the drugs, because normal students fall asleep rapidly, sleep soundly, and do not waken during the night Only after pentobarbitone gr 3 did increased depth of sleep become apparent From questions 4 and 5 it is seen that in about a third of the students pentobarbitone gr 1½ caused increased difficulty in waking and drowsiness next morning Fewer subjects noted difficulty in waking after glutethimide 500 mg , but the same proportion, about a third, complained of drowsiness next day Other after effects were rare with these two drugs, but pentobarbitone gr 3 caused a large number of unpleasant after effects (table II), and is clearly unsuitable for administration to young ambulant subjects

TABLE III—SIGNIFICANCE OF DIFFERENCE BETWEEN DRUGS (χ^2 test)

Question	Drugs compared	Probability (P) that observed difference is not significant
1	C and P3 G and P3	<0 001 <0 02
2	No significant differences	
3	No significant differences	
4	C and P1½ C and P3 P3 and G	<0 01 <0 001 <0 05
5	C and P3 C and G P1½ and P3 P3 and G	<0 001 <0 02 <0 01 <0 01

All other differences not significant

C = control.
P1½ = pentobarbitone gr 1½
P3 = pentobarbitone gr 3
G = glutethimide 500 mg

Objective Study (Men)

109 students entered the experiment, but complete records for all four drugs were obtained from only 9 Satisfactory records for three substances (excluding pentobarbitone gr 3) came from 30 others Many records were rejected because the stimulus was either "inadequate" or "excessive" as previously defined, or for other reasons listed in table IV The gr 3 dose of pentobarbitone was given to only a quarter of the subjects These were all during first tests, and with the smaller water load This departure from the original experimental plan must be borne in mind in interpreting the results, but it is unlikely to have introduced serious error Incomplete sets of records could not be used in the final analysis

TABLE IV—CAUSES OF INCOMPLETE RECORDS

No submitting at least one return	109
No returning complete set of four acceptable results	9
No returning set of three acceptable results (i e other than for pentobarbitone gr 3) excluding the above	30

Cause of default	Control	Pentobarbitone gr 1½	Pentobarbitone gr 3	Glutethimide 500 mg
No return submitted	20	19	75	16
Doubt about capsule issued	1	3	0	0
Water load inadequate	15	19	12	17
Water load excessive	6	1	3	6
Rash after pentobarbitone (one subject)	1	1	0	1
Total	43	46	90	40

TABLE V—RESULTS FOR FOUR TEST SUBSTANCES IN 9 SUBJECTS

Subject	Sequence of drugs	Value (log t × log v) after			
		1 (Control)	2 (Pentobarbitone gr 1½)	3 (Pentobarbitone gr 3)	4 (Glutethimide 500 mg)
1	3–1–2–4	4 63	5 07	7 40	7 41
2	3–2–1–4	5 44	8 04	8 67	5 60
3	3–2–4–1	5 56	7 38	7 21	6 92
4	3–1–2–4	5 49	5 52	5 66	5 98
5	3–1–2–4	7 45	7 63	7 44	7 74
6	3–4–1–2	7 80	8 00	8 10	7 74
7	3–4–1–2	7 39	7 58	7 69	7 81
8	3–2–1–4	5 21	5 27	6 03	7 27
9	3–1–4–2	5 62	7 59	8 22	7 57

The full data obtained from giving four test substances to 9 subjects are set out in table V, and table VI shows the analysis of variance It is seen that differences between individuals contributed more to the total variance than did differences between drugs A significant difference between the effects of the drugs was apparent (P = 0 01) When the drugs were compared in pairs, it was found that there were significant differences between each of the drugs and the placebo and between the two dose-levels of pentobarbitone The difference between 500 mg of glutethimide and pentobarbitone gr 1½ was not significant The difference between glutethimide 500 mg and pentobarbitone gr 3 just failed to reach the 5% level of significance in this small series

In the analysis of 39 sets of results (including these 9) in which the placebo, pentobarbitone gr 1½, and glutethimide 500 mg were compared (table VII) a significant difference between the drugs was again found (P = 0 001) A comparison by pairs showed that both drugs differed significantly from the placebo, but not from one another

TABLE VI—ANALYSIS OF VARIANCE—SMALLER SERIES

Source of variation	Sums of squares	Degrees of freedom	Mean squares	Ratio
Between drugs	8 71	3	2 90	Drugs to residual
Between individuals	20 59	8	2 57	
Residual	15 18	24	0 63	F = 4 72
Total	44 48	35		

F 0 01 = 4 72

TABLE VII—ANALYSIS OF VARIANCE—LARGER SERIES

Source of variation	Sums of squares	Degrees of freedom	Mean squares	Ratio
Between drugs	8 50	2	4 25	Drugs to residual
Between individuals	50 85	38	1 34	
Residual	45 38	76	0 60	F = 7 08
Total	104 73	116		

F 0 001 = 7 70

Discussion

The response of normal subjects to a hypnotic cannot give a complete picture of what is to be expected from the drug in clinical practice But the subjective and objective appraisal of glutethimide in different subjects lead to the same conclusion—that this drug in a dose of 500 mg was equivalent to pentobarbitone gr 1½ in hypnotic effect, and was slightly less liable to cause difficulty in waking Clinical studies of glutethimide have led to rather similar conclusions, and Rushbrooke et al (1956) said that their patients in general practice found that glutethimide 500 mg was comparable to cyclobarbitone 200 mg

Summary and Conclusions

A subjective test in 34 female students showed that glutethimide 500 mg had about the same effect as pentobarbitone gr $1^1/_2$ in increasing the depth of sleep, and was slightly less prone to cause difficulty in waking

An objective study in male students, based on the measurement of resistance to waking from bladder stimulation, showed that glutethimide 500 mg was about as potent a hypnotic as pentobarbitone gr $1^1/_2$

This trial supports the validity of the method of comparing the potency of hypnotic drugs proposed in the preceding paper

I wish to express my sincere thanks to the students who took part in these experiments I also thank Miss Sheila Grace for her help and Dr S D Silvey for advice on the statistical analysis Glutethimide was supplied by Messrs Ciba Laboratories, Horsham, and the special capsules were prepared by Messrs John Tye & Sons

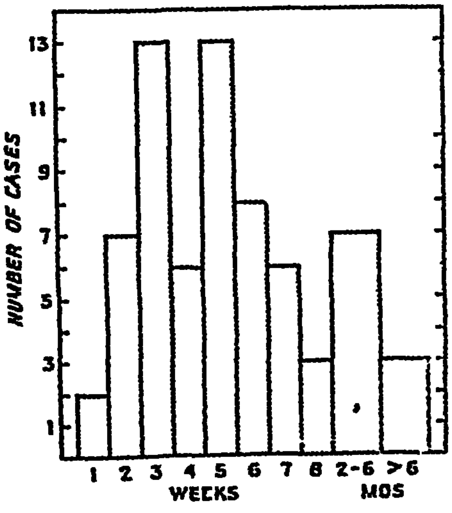
PENICILLIN IN THE TREATMENT OF LACTATIONAL BREAST ABSCESS

L R De Jode
M B Lond, F R C S
SURGICAL REGISTRAR, LONDON HOSPITAL

Breast abscess remains one of the more disabling forms of sepsis For the mother it may mean a prolonged illness, a maimed breast, and one or more ugly scars, and for the child, an unfortunate interruption of breast feeding

The high hopes of controlling this distressing illness raised by the advent of antibiotics have not been realised, and the number of cases treated annually at the London Hospital remains approximately constant In an attempt to assess the effect of antibiotics, especially penicillin, in modifying the course of the illness, 68 consecutive cases treated at *the London Hospital between 1953 and 1955* were analysed, and the results are presented here



Interval between parturition and breast abscess

Of these 68 lactating women, 35 were delivered in hospital and 33 at home The intervals elapsing between delivery and the *onset of the* breast abscess are shown in the accompanying figure, from which it will be seen that, as previously noted by Walsh (1949), a substantial number of abscesses developed when the patients had left hospital and were under the care of their general practitioner During the same period the surprisingly large number of 32 non-lactational cases of breast abscess were also treated

TABLE I—ANTIBIOTICS USED

Antibiotic	No of cases
Penicillin only	36
„ and other antibiotic *	8
Other antibiotics only †	4
No antibiotic	20
Total	68

* Aureomycin 7 cases chloramphenicol 1 case
† Oxytetracycline, aureomycin chloramphenicol and streptomycin 1 case each

Bacteriology

The infecting organism was cultured from the pus in all except 3 cases In 64 cases *Staphylococcus pyogenes* was grown and its sensitivity in vitro to penicillin determined A non hæmolytic streptococcus was cultured in 1 case When delivery took place in hospital 90% of the staphylococci cultured were resistant to penicillin, whereas when *delivery took place at home* 71% were resistant

Antibiotics

These patients were treated by a number of general practitioners and several surgical and obstetric firms, hence there was no general policy for the use of antibiotics The cases were divided into two groups those in which antibiotics were given before incision of the abscess and those in which they were not Table I shows that 48 cases were treated with *antibiotics* and 20 not Penicillin was used in 44 cases, but in 8 of these another antibiotic, usually aureomycin, was also given Of the 48 cases treated with antibiotics only 4 were not treated with penicillin The number of cases treated with other antibiotics was too small for any conclusions of value to be drawn

TABLE II—COMPARISON OF AVERAGE NUMBER OF INCISIONS *AND HEALING TIME IN ANTIBIOTIC TREATED AND UNTREATED* CASES

Treatment	No of cases	Average no of incisions	Average healing time (wk)
1 No antibiotic	20	1·0	3·9
2 Penicillin (organism resistant)	10	1·7	6·3
3 Penicillin (organism sensitive)	4	1·2	4·7
Difference between 1 and 2		0·7 (s e ±0·4)	2·4 (s e ±1·0)

s e standard error of difference between means

Criteria of Comparison

Two criteria were used to assess the effect of penicillin on the course of the illness the total duration of the illness from first symptom to final healing, and the number of incisions necessary before this took place The results are shown in table II

In the 20 cases not treated with antibiotics before drainage the average healing time was 3·9 weeks and the average number of incisions 1·0

In 4 cases the organism was subsequently proved to *be sensitive to penicillin, in them the healing* time was 4·7 weeks and the average number of incisions 1·2 In the 10 cases treated with penicillin in which later examination showed the organism to be penicillin resistant the average healing time was 6·3 weeks and the average number of incisions 1·7

Case-reports

Certain cases were of particular interest as illustrating *the effect of antibiotics on the course of the illness*

Case 1 —The patient, aged 19, developed painful red flushed breasts with pyrexia (102°F) on the 10th day after a normal delivery in hospital. After a 4-day course of soluble penicillin 500,000 units b.d. the pain settled and the temperature fell to normal. The child was weaned, and the patient was discharged home. She was referred to hospital 14 days later with an abscess in her right breast, and an "enormous multilocular cavity" was drained. 2 days later she developed further abscesses in her left breast, and two large cavities were drained on this side. A month later the abscess recurred in the left breast, requiring two further incisions. In every specimen a staphylococcus resistant to penicillin was grown. The total period of disability in this case was 10 weeks.

Case 2.—The patient, aged 26, complained of pain and tenderness in her left breast on the 7th day after a normal delivery in hospital. A localised area of tender induration was palpable, and she was given a course of soluble penicillin 500,000 units b.d. with little improvement. Aureomycin was substituted on the 3rd day, and the condition appeared to resolve. She was discharged home and continued breast-feeding. 2 weeks later, however, pain recurred, and she was readmitted with an abscess in her left breast. This was incised and a staphylococcus insensitive to penicillin was grown. 5 days later a further abscess required drainage and then healed. The period of disability was 5 weeks.

Case 3.—The patient, aged 30, developed pain and swelling in her right breast two weeks after normal delivery in another hospital. After a 4-day course of penicillin the pain and swelling subsided, and she was discharged home to continue breast-feeding. A week later she was referred to the London Hospital and admitted. Her right breast was extremely tense and tender, but after expression of milk no definite lump was felt. Pus, however, was aspirated from the lower medial quadrant, and on incision a large single cavity was found deep in the breast. A penicillin-resistant staphylococcus was cultured. Lactation was suppressed with stilbœstrol. 16 days later a further small abscess in the right breast required incision. The total period of invalidism was 5 weeks.

Case 4.—The patient, aged 28, developed pain and swelling in her left breast 3 weeks after a normal delivery of a second child at home. She was treated by her doctor for 12 days with procaine penicillin without improvement and then referred to surgical outpatients. She had an extensive tender indurated area deep to her left nipple and extending out in all quadrants. A large multilocular abscess was incised, and its wall was noted to be thick and very hard. Pus grew *Staph. pyogenes* insensitive to penicillin. The period of disability was 5 weeks.

Case 5.—The patient, aged 23, was treated by her doctor for right flushed breast, which developed a month after normal delivery in the London Hospital. After a 3-day course of soluble penicillin 500,000 units b.d. the condition gradually subsided and she continued breast-feeding. 2 months later pain recurred and lactation was suppressed with stilbœstrol. A lump then appeared in her right breast, and she was referred to the London Hospital, where a large indurated non-tender mass was found in the lower inner quadrant of her right breast. After application of a kaolin poultice for 24 hours fluctuation was found, and two incisions produced nearly half a pint of pus. The abscess wall was very vascular and bled briskly, an abnormal ooze persisting for 48 hours. Surprisingly a staphylococcus sensitive to penicillin was grown. The total period of disability was 2 months.

Case 6.—The patient, aged 23, developed a painful right flushed breast with pyrexia (102 F) on the 9th day after a normal delivery in the London Hospital. After a 3-day course of soluble penicillin 300,000 units daily the condition appeared to resolve, the patient's temperature fell to normal, and she was discharged home. 15 days later a painful lump reappeared and she received a further 5-day course of soluble penicillin 300,000 units b.d. without improvement. She was then referred to the London Hospital, and a tender, very hard and non-fluctuant mass was found in the upper outer quadrant of her right breast with redness of the overlying skin. Penicillin was discontinued, and kaolin poultices were applied daily. The condition remained indolent until 3 weeks later, when it was considered that fluctuation was present, and an incision was made into "a large fibrous mass" containing a small cavity but no pus. 2 weeks later a fluctuant area developed here and was incised, a small quantity of pus being evacuated. A profuse growth of *Staph. pyogenes* insensitive to penicillin was cultured. The residual indurated area in the breast was treated with short-wave diathermy, and the condition eventually healed 6 weeks later. The period of disability was 3 months.

Discussion

Today many of the dreaded complications of uncontrolled sepsis have been eliminated or at least mitigated. Mutilated hands resulting from severe finger infections, useless joints after septic arthritis; fulminating septicæmias, the sequel of osteomyelitis, no longer fill septic wards. Nevertheless, every therapeutic advance poses its own set of problems, and antibiotics are no exception. When penicillin became generally available it was thought that its use would greatly lessen both the duration of breast abscess and the need for surgical incision (Florey et al. 1946).

It is indeed remarkable that penicillin continued in the present series to be the antibiotic favoured by both general practitioner and in hospital treatment, despite the handicap of its having to be used parenterally and despite the availability of a variety of other potent antibiotics. The evidence presented above, however, suggests that neither healing-time nor the number of surgical incisions has been lessened. Where the organism is insensitive, the healing-time is lengthened and the number of incisions increased. Several factors may be responsible for this.

Firstly, the conditions in the lactating breast are peculiarly favourable to the rapid multiplication of pathogenic organisms and the early formation of an abscess.

Secondly, the chance of the responsible organisms being insensitive to penicillin is always considerable and, when the patient has been delivered in hospital, almost certain. Barber and Burston (1955) found that, in 89% of babies leaving a maternity unit, a penicillin-resistant staphylococcus could be grown from the anterior nares. Not only is there, therefore, a considerable chance of penicillin being useless from the start, but also, once pus is formed, there is little likelihood of cure without drainage, whatever the antibiotic used. Moreover, apart from penicillin therapy's being often pointless, its injudicious use may complicate treatment of the established abscess.

Some of the disadvantages are illustrated in the cases cited above. In cases 1, 2, 3, 5, and 6 the symptoms and signs of infection completely disappeared after treatment with penicillin, only to recur later, by which time large abscesses had formed.

Case 5 was of particular interest. When the patient eventually presented as an outpatient, a large, indurated, and notably non-tender mass was found which clinically resembled a carcinoma. This difficulty has been noted by Stammers (1953) and is due to the masking of the signs of inflammation.

The findings in case 6 were somewhat similar, and it was only after the discontinuance of penicillin and the daily application of kaolin poultices for 3 weeks that fluctuation became evident. When the breast was finally incised, a hard fibrous mass was found surrounding a small cavity but little pus. Healing was considerably delayed by this fibrotic reaction, which eventually disappeared after a course of short-wave diathermy.

The excessive formation of vascular granulation tissue too may lead to excessive hæmorrhage when the abscess is incised, as in case 5. These features have also been noted by Mills (1953).

The masking of the signs of inflammation may lead to serious delay in instituting drainage, with the result that an excessive amount of breast tissue is destroyed, amounting in some cases to functional mastectomy.

A further consequence of this destruction of breast tissue is the increased liability to further breast abscesses, particularly after later pregnancies.

It therefore seems reasonable to restrict the use of penicillin to early cases of acute mastitis, and then only when the mother has not been delivered in hospital and there is therefore a reasonable chance of dealing with an organism sensitive to penicillin If there is no response within 48 hours, its use should be discontinued because of the difficulties already mentioned If a satisfactory response is obtained, the patient must still be kept under close supervision to ensure that the condition has been cured and not merely masked When an abscess has already formed, early and effective drainage is the surest way of obtaining early healing

Summary

Of 100 consecutive cases of breast abscess treated at the London Hospital between 1953 and 1955 32 were non lactational The 68 lactational cases were analysed with particular reference to penicillin therapy

In this series penicillin continued to be the antibiotic most commonly used both by general practitioners and in hospital

Where the patient had been delivered in hospital 90% of the staphylococci cultured were insensitive to penicillin, and in other cases 71% were insensitive

Where the organism was insensitive to penicillin both the number of surgical incisions required and the healing-time were increased in comparison with the cases in which no penicillin was given

I wish to thank the surgical and obstetric staff of the London Hospital for permission to cite their cases, and Mr A R Anscombe for much helpful criticism and encouragement

BRONCHIAL LAVAGE

G F TROBRIDGE
M D Birm, M R C P E
ASSISTANT CHEST PHYSICIAN, HAWKMOOR CHEST HOSPITAL, BOVEY TRACEY, DEVON

BRONCHIAL lavage, as a means of obtaining material for the culture of tubercle bacilli, has already been described several times (Lees et al 1955, Spencer Jones 1956) The present work, which confirms previous findings, has led to a much simpler technique which can be quite easily used by nurses

All patients admitted to this hospital for investigation of respiratory disease and who had no sputum were subjected, as soon as possible after admission, to three daily gastric residue and three daily bronchial lavage examinations As all specimens were collected within a week and usually within three days, the two series are comparable

Technique

The technique is simpler than previous methods and carries less risk to the operator For half an hour before examination the patient sucks an amethocaine hydrochloride ('Decicain') 100 mg lozenge (two half tablets, at quarter hour intervals, is most effective) He sits in a chair leaning backwards and to one side (fig 1) The operator stands behind the patient and with the left hand holds the patient's tongue The patient is told to breathe slowly and deeply and not to cough or swallow while 10 ml of normal saline is poured slowly on to the tongue so that it trickles back through the larynx and down the trachea The patient now coughs into the wide mouthed jug which was placed in his hands at the beginning The procedure is then repeated for the second side It is very important to acquire a technique of pouring the saline slowly and steadily, otherwise the patient will cough The saline should be poured as fast as is possible without producing cough—usually ten to twenty seconds for 10 ml The best method is to hold a syringe as in fig 2 The operator should, of course, be protected by gown and mask, but risks of infection are less when standing behind the patient than with the other methods of bronchial lavage described previously The specimen is then transferred to a bottle A satisfactory specimen always contains some solid particles, and they may be plentiful even from a healthy chest The specimen is then cultured in the laboratory in the same way as a gastric residue specimen, except that neutralisation is omitted

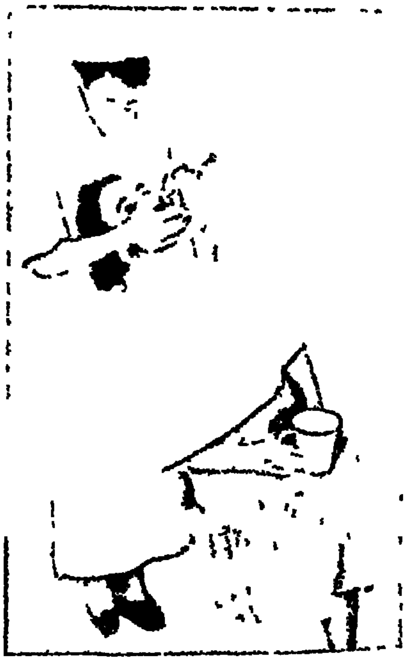

Fig 1—Position of patient.

Results

70 patients took part in this trial, and all had three bronchial lavage and three gastric residue examinations 41 had pulmonary tuberculosis, active or inactive, 9 had pleural effusions, and the remaining 20 had other respiratory conditions Table I shows the number of patients in each group from whom positive cultures for tubercle bacilli were obtained by bronchial lavage and gastric residue examinations No case was positive on gastric residue which was not also positive on bronchial lavage

To determine the most reasonable number of examinations to which a patient should be subjected, the proportions of patients first found to be positive by each of the three tests was recorded The bronchial lavage and gastric residue series have here been regarded as separate investigations, but the cases of pulmonary tuberculosis and pleural effusion have been added together (table II

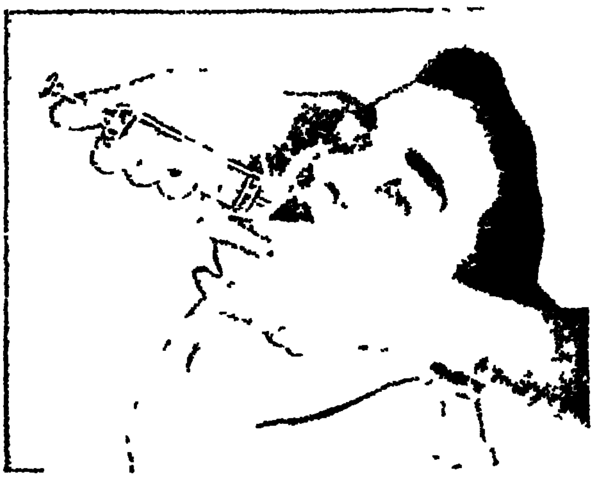

Fig 2—Position of syringe

TABLE I—RESULTS OF EXAMINATIONS

Diagnosis	No of cases	No of cases with positive cultures	
		Bronchial lavage	Gastric residue
Pulmonary tuberculosis	41	14 (*34%*)	3 (*7%*)
Pleural effusion	9	2 (*22%*)	1 (*11%*)
Other respiratory conditions	20	0	0

TABLE II—THE FIRST POSITIVE CULTURE

Examination giving first positive culture	No of patients	
	Bronchial lavage	Gastric residue
1st	9 (*18%*)	4 (*8%*)
2nd	6 (*12%*)	0
3rd	1 (*2%*)	0
Total	16 (*32%*)	4 (*8%*)

From these tables it is apparent that bronchial-lavage examination was four times as efficient as gastric residue examination in the recovery of tubercle bacilli, and that the majority of positive cases can be found by two bronchial lavages

The results of this trial suggested the possibility that tubercle bacilli contaminating a healthy respiratory tract might be recovered by bronchial lavage giving a false positive result It was therefore decided to try the test in healthy volunteers who all had normal chest X-rays and no past history of pleural or pulmonary tuberculosis The tests were arranged at times when it was thought that maximum contamination was likely—e g, after bed-making 105 lavages were made in 30 nurses, but there was not one positive result

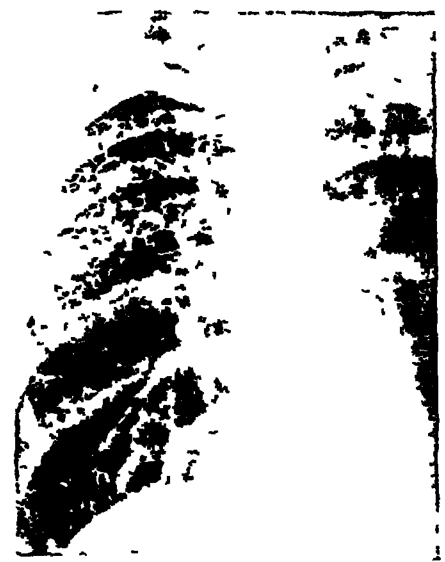

Fig 3—Bronchogram

The negative results in healthy volunteers and non tuberculous patients show that false positives from contamination of the air-passages by tubercle bacilli are unlikely, and that a positive result means active disease (apart from very rare laboratory errors)

During these examinations it was suggested that the saline went no further than the larynx Accordingly, after a normal bronchial lavage and without further anæsthesia, one of the volunteers had 20 ml of propyliodone (' Dionosil ') poured over the back of the tongue (straight from the bottle) Positioning was carried out as for bronchography, fig 3 shows the bronchogram obtained This also demonstrates the efficiency of the anæsthesia, which has since been used in obtaining satisfactory routine bronchograms in coöperative patients without any other premedication

Conclusions

In this hospital we have been so satisfied with the ease and accuracy of the tests that bronchial-lavage has now replaced gastric-residue examinations The ward sisters carry out the tests without difficulty Cases under treatment may seem to remain positive a little longer when bronchial-lavage examinations are used, but this is due to increased sensitivity of the test

At least two lavage examinations are necessary for accuracy, there is no doubt that the second examination is more thorough than the first, because the patient cooperates better

The great majority of those who underwent the examinations, and of those who performed them, preferred bronchial-lavage to gastric-residue examinations

Summary

A parallel comparison of bronchial-lavage (by a simplified method), and gastric-residue examination showed that bronchial lavage was four times as efficient in isolating tubercle bacilli

A control series of healthy volunteers yielded no false positive results

A simple technique for bronchography, suitable for certain patients, has resulted from this work

I wish to thank Dr R L Midgley for encouragement and advice, Dr B Moore who did the bacteriological work, and all the volunteers who made this investigation possible

RELIEF OF ŒDEMA AND HIGH BLOOD-PRESSURE BY CONCENTRATED HUMAN SALT-POOR SERUM-ALBUMIN

IN ELLIS TYPE-II NEPHRITIS

A G Edwards
M B Lpool
FLYING OFFICER, MEDICAL BRANCH, R A F

THE value of concentrated human serum-albumin has been extensively studied in the U S A, mainly by Cohn et al, Eckhardt et al (1948), and Janeway et al (1944), and as far back as 1942 the first standard preparation for the Armed Forces was tested In the U K it has been studied by Martin (1954) Most of the early work was directed towards the treatment of shock and burns, and its value in hypoproteinæmia was mainly in the treatment of malnutrition and hepatic cirrhosis Recorded cases of its use in the nephrotic syndrome are relatively few (Janeway et al 1944, Martin 1954, Ferguson 1955)

Case-report

A girl, aged 19, was seen for the first time on June 14, 1955, complaining of œdema of the face and trunk for two days, œdema of the ankles for three weeks, and severe headaches for six months There was no previous history of either scarlet fever or renal disease

On examination she was pale and had gross anasarca, her heart sounds were normal and blood pressure was 130/90 mm Hg, there was no retinopathy Laboratory investigations showed plasma proteins 3 91 g per 100 ml (albumin 1 25 g per 100 ml, globulin 2 66 g per 100 ml), cholesterol 610 mg per 100 ml, non protein nitrogen 33 mg per 100 ml, and hæmoglobin 86% The urine contained many red blood cells and epithelial casts and an average of 12 g of albumin (Esbach's method) per litre in 24 hr

Treatment —The patient was treated with high protein salt free diet with restricted fluids, and both mersalyl and acetazolamide were tried with some effect

Readmission —Four months later she was readmitted with similar symptoms, her urine containing 15 g of albumin per litre on admission Other investigations showed plasma proteins 3 72 g per 100 ml (albumin 1 52 g per 100 ml, globulin 2 20 g per 100 ml), albumin globulin ratio 0 7, non protein nitrogen 27 mg per 100 ml Urine contained granular casts and some red blood cells

Treatment —To encourage absorption of peripheral œdema, 400 ml of double strength plasma was transfused, with only slight improvement The induction of malaria pyrexia was contra indicated owing to the presence of red blood cells in the urine Treatment with cortisone 300 mg initially, followed by 50 mg daily was started, but the patient developed pyrexia and bilateral pneumonic consolidation with effusion and pericarditis So the cortisone therapy was abandoned, and after prolonged antibiotic treatment she gradually improved During the high pyrexia the peripheral œdema subsided, but there was no coincident change in electrolyte or in serum protein levels The patient was discharged on a high protein diet

Readmission —The patient was readmitted on April 13 1956, with anasarca, which had been increasing for two weeks

On examination her blood pressure was 170/120 mm Hg and her heart rate showed a gallop rhythm at the apex There were slight exudates in the fundi The amount of albumin in the urine was 14 g per litre in 24 hr Other investigations showed serum proteins 3 94 g per 100 ml (albumin 1 45 g per 100 ml , globulin 2 49 g per 100 ml), albumin globulin ratio 0 7, non protein nitrogen 22 mg per 100 ml No casts were found in the urine

Treatment —Given 1000 ml of triple strength plasma the patient had a diuresis of only 90 oz in 24 hours It was then decided to transfuse human serum-albumin set up in 100 ml transfusion bottles containing 25 g of albumin per 100 ml 200 ml was transfused in $1^1/_2$ hours, and during the next 12 hours the patient passed 227 oz of urine containing about 12 g of albumin per litre Her condition was much improved serum proteins 3 01 g per 100 ml (albumin 1 23 g per 100 ml , globulin 1 78 g per 100 ml), albumin globulin ratio 0 7, non protein nitrogen 18 mg per 100 ml Since there was still slight residual peripheral œdema 100 ml more of the albumin was transfused in 20 minutes, followed by a diuresis of 132 oz in 24 hours, when no œdema could be discovered (blood pressure 150/100 mm Hg) There was no symptom of overloading the circulation , nor did the blood pressure rise Her serum proteins were 6 12 g per 100 ml (albumin 2 29 g per 100 ml globulin 3 83 g per 100 ml), albumin globulin ratio 0 6, non protein nitrogen 28 mg per 100 ml , Hb 83% On April 24 the patient started a 250 g protein salt free diet and was given a further 200 ml of albumin intravenously in 45 minutes, the only side effect being a slight headache, and the diuresis being 101 oz in 24 hours Her serum proteins were 4 96 g per 100 ml (albumin 2 88 g per 100 ml , globulin 2 08 g per 100 ml), albumin globulin ratio 1 4, non protein nitrogen 23 mg Four days later, the total serum protein level had risen to 6 59 g per 100 ml though the albumin globulin ratio was still 0 9 Another transfusion of 100 ml of serum albumin in half an hour was given, producing a slight headache and a slight change in the serum protein level There was a further diuresis of 170 oz She was discharged without œdema and with a blood pressure of 130/90 mm Hg There was no change in the retinopathy

Follow-up —The patient returned a week later when œdema of her ankles had returned Her urine still contained about 12 g of albumin per litre and her blood pressure had risen to 150/110 mm Hg, but exudates were no longer present in her fundi Her serum protein level was 3 63 g per 100 ml (albumin 2 08 g per 100 ml , globulin 1 55 g per 100 ml), albumin globulin ratio 1 3, non protein nitrogen 26 mg per 100 ml Her urine contained epithelial debris and a few red blood cells

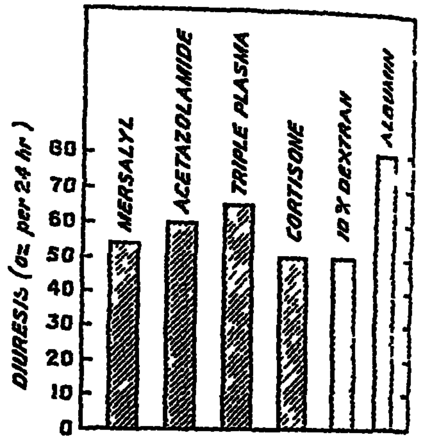
Readmission —A week later she was readmitted for further treatment , her blood pressure having risen to 170/120 mm Hg and œdema having appeared again Her serum proteins were 3 96 g per 100 ml (albumin 1 34 g per 100 ml , globulin 2 62 g per 100 ml) and albumin globulin ratio 0 5

Treatment —Double strength 10% salt free dextran was transfused but had to be discontinued because of severe headache and vomiting The diuresis was only 90 oz in 24 hours Later 300 ml of the serum albumin was transfused without causing headache , it did not give so dramatic a diuresis as previously (103 oz in 24 hours) but relieved the œdema The blood pressure on discharge was 130/90 mm Hg serum proteins 3 12 g per 100 ml (albumin 1 25 g per 100 ml globulin 1 87 g per 100 ml), albumin globulin ratio 0 7, and non protein nitrogen 33 mg per 100 ml

Follow up —The patient has since visited for examination and her blood pressure was found to have returned to 170/130 mm Hg and much of the œdema had returned The accompanying figure shows the relative diuretic values of the various diuretics used

Discussion

Characteristically, Ellis type II nephritis occurs in young patients without previous history of any severe streptococcal infection The onset is insidious, often with vague malaise followed by facial or ankle œdema, which although undergoing remissions and exacerbations gradually increases to anasarca Hypertension may or may not be present, and retinopathy, apart from macular œdema, is uncommon There is much albumin in the urine, often well over 20 g per litre in twenty four hours and the amount of urine excreted is small Casts are common in the urine However, there is no general renal insufficiency, the non-protein nitrogen, urea clearance and urea concentration being usually normal The blood shows a low total protein level with a reversal of the albumin globulin ratio and a raised blood cholesterol level



Diuretic values of diuretics used

The main feature of the present case was anasarca, but the mild hypertension and slight renal exudates are also of note because they are uncommon in Ellis type II nephritis *On each occasion that the human serum albumin was used there was a dramatic relief of œdema* because the corrected osmotic pressure of the plasma caused a diuresis unsurpassed by that due to standard diuretics , *also the blood-pressure was lowered*, and overloading symptoms were extremely mild This is interesting because other workers have found the use of human serum albumin to produce such symptoms as severe headache, gross venous engorgement, and a slight rise in blood-pressure But it appears that their patients were treated with human serum-albumin together with a diluent, usually dextran, whereas the present patient was treated with concentrated human serum albumin I feel that this is of significance because it is only necessary to replace lost protein (essentially the albumin fraction of the plasma), additional fluid causing only circulatory embarrassment The rapidity of transfusion had no untoward effect on the patient, probably owing to the small volume transfused at a time It was also extremely difficult to correct the reversal of the albumin globulin ratio, and the effect of the human serum albumin was transient, lasting only a few days

Summary

In a case of Ellis type II nephritis concentrated human salt poor serum albumin produced a much better diuresis than did plasma and dextran The blood pressure was lower after this treatment on each occasion

Concentrated human serum albumin has only a transient effect , for this reason it is of no use in maintenance therapy

I wish to thank Dr C M Miller for permission to publish, Dr L Horwich for much helpful advice, and the [illegible] officer at the U S A A F base at Sealand for the gracious gift of 1200 ml of serum albumin

Preliminary Communication

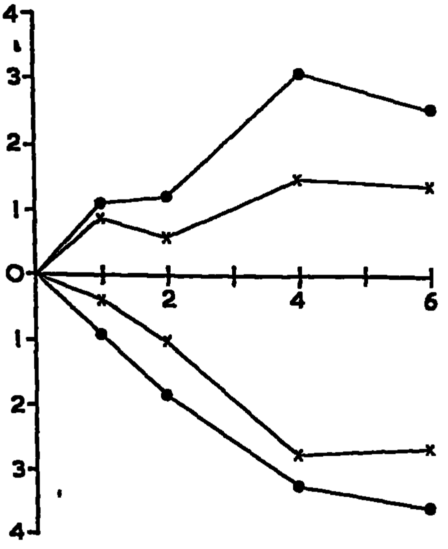
THE EFFECT OF QUINIDINE ON POTASSIUM FLUX

QUINIDINE has been known since the work of Frey in 1918 as a substance which arrests atrial (auricular) fibrillation Recently fibrillation has been produced in the atria of the rabbit heart suspended in a bath To produce fibrillation three things were necessary (*a*) acetylcholine in concentrations from 3 to 8×10^{-4} g per ml , (*b*) electrical stimulation at a rate from 600 to 800 per minute , and (*c*) a reduction of the K^+ in the bath to 1 4 mM per litre When fibrillation was produced, it persisted after the stimulation was stopped [1]

Holland [2] has measured the net amount of K^+ leaving the atria He changed the bath fluid to one containing 0 35 mM per litre of K^+ and left the atria in it for five minutes He removed the fluid and measured the K^+ by a flame photometer He found that when stimulation was applied at increasing rates in the absence of acetylcholine the net K^+ loss rose very little In the presence of acetylcholine, however, an increasing rate of stimulation produced an increasing potassium loss, and when it reached a certain figure, fibrillation occurred

When the isolated atria are beating spontaneously, quinidine (10^{-5} g per ml) slowly reduces the rate and amplitude until the beats stop Armitage [3] has recently observed that when the amount of potassium in the solution bathing the atria was reduced, the contractions started again These observations suggested that quinidine affected the permeability of the cell membrane to potassium, perhaps diminishing the potassium flux

We have therefore carried out experiments to test this, and have used human red cells When blood is freshly drawn, the cells are rich in K^+ and poor in Na^+ Blood was therefore cooled to 0°C, and kept at this temperature for 3–5 days during which the cells lost K^+ and gained Na^+ The blood was then incubated at 37°C for several hours , at this temperature the metabolic processes which drive Na^+ out of the cell and which raise the concentration of K^+ within the cell were active To some of the blood quinidine was added (25–250 µg per ml), and the rate of rise of K^+ in the cells in blood containing quinidine was compared with the rate of rise in control blood Ten experiments were carried out in six heparin was added to the blood , in three the blood was defibrinated , and in one the cells were separated from plasma and suspended in Ringer's solution In each experiment it was observed that the presence of quinidine diminished the uptake of potassium A similar result was obtained in two experiments in which chloroquine was used The accompanying graph shows the mean results The observations also showed that sodium was driven out of the cells more slowly in the presence of quinidine



The abscissa is time in hours The ordinate for the two curves above is the mean increase in potassium (mM per 100 g hæmoglobin) of red cells incubated at 37°C. The black circles represent control figures the crosses represent figures in the presence of quinidine The ordinate for the two curves below is the mean decrease in sodium (mM per 100 g hæmoglobin) of red cells Black circles are control figures the crosses represent figures in the presence of quinidine

This finding makes it seem likely that the action of quinidine in arresting fibrillation is due to a reduction of the permeability of the cell membrane to potassium, and probably to sodium also

Medical Societies

HEBERDEN SOCIETY

THE society met in London on Feb 22

Shoulder-hand Syndrome

Dr R P HICKEY showed a case of bilateral shoulder hand syndrome The involvement on the right side, which included the right elbow, followed a traumatic right hemiplegia, while the involvement of the left side followed herpes zoster of the cervical 5th–7th nerve distributions

Lupus Erythematosus

Dr A. BEARDWELL, Dr A G BECKETT, and Dr C FELDMAN each showed patients with probable disseminated lupus erythematosus associated, respectively, with lung changes and pneumothorax, with hepatitis and peripheral neuropathy, and with polyarthritis and leg ulceration

Polymyositis

Dr A T RICHARDSON described the diagnostic features of polymyositis based on his findings in twenty one patients The histological findings in the muscles in polymyositis included patchy muscle fibre degeneration and widespread cellular infiltration, and contrasted with the focal infiltration of rheumatoid arthritis or the widespread degeneration without much infiltration in the myopathies It could not be differentiated from the changes seen in dermatomyositis Clinically, too, there was no clear dividing line between polymyositis and dermatomyositis , indeed, one of his myositis cases showed a scaly erythema, another had calcinosis, and a third developed scleroderma like changes In three other cases where there was no suggestion of skin involvement, symptoms included dysphagia One case was notable for the extreme rapidity with which muscular contractures developed Seven of his cases had been previously diagnosed as "myopathy of late onset" Polymyositis was usually thought of as involving mainly proximal muscles , but he had found that the forearm muscles were usually involved as well, and were often a suitable site for testing electromyographically There was evidence of impairment of action potentials on voluntary contraction of affected muscles, but in addition the electromyogram showed rheobase changes of denervated muscle and also evidence of spontaneous lower motor neurone activity The combination of muscle wasting with both a muscle fibre and a lower motor neurone lesion was diagnostic of myositis, and it was interesting that, as testing was proceeding, most of the cases which had been referred to him as myopathy of adult life were proving to have a myositis

Serum-proteins

Dr J H JACOBS and Mr R L MARKHAM showed a two dimensional zone electrophoresis of serum proteins They had used albumin impregnated paper (to minimise absorption of the test proteins) and, after making a conventional separation at pH 8 6, transferred the albumin, α globulin, and β globulin fractions to another paper and ran the separation at pH 4 5 at right angles to the original direction On staining for polysaccharides they obtained clear and isolated spots representing the α_1 and α_2 glycoproteins, which could be estimated semi quantitatively These spots were sometimes oval and sloping, especially in rheumatoid arthritis, suggesting they were not single substances The estimate of α_2 glycoproteins in rheumatoid arthritis correlated quite well with the clinical condition of the patient as judged by the erythrocyte sedimentation rate, but the α_1 glycoproteins seemed to vary independently of both Somewhat similar changes had been found in various other diseases

Sheep-cell Agglutination Tests

Dr E V HESS had found that sheep cell agglutination tests for rheumatoid arthritis had given positive results in 48% of cases of lupus erythematosus, 33% of cases of polyarteritis nodosa, 26% of cases of scleroderma, and one out of five cases of myositis Using a modification of Ziff's euglobulin precipitation technique she had examined both precipitate and freeze dried supernatant for agglutinating activity In rheumatoid arthritis this activity usually remained in the precipitate, but in some positive cases of lupus the activity remained in the supernatant The distinction was not completely reliable but might be helpful where the diagnosis between rheumatoid arthritis and lupus was in doubt She had been impressed with the tendency for lupus patients to have a positive agglutination test if they had joint involvement It seemed likely, also, that this group gave biological false positive results on Wassermann testing somewhat more commonly than the cases of lupus in which the agglutination test was negative In rheumatoid arthritis the agglutinating factor was associated with the gamma globulins In a positive case of lupus, however, she had found that the activity lay in the β globulin zone

SOCIETY OF UNIVERSITY SURGEONS

THE 18th annual meeting of the Society of University Surgeons was held on Feb 7–9 at Columbus, Ohio, under the presidency of Dr HAROLD A ZINTEL Of the 40 papers 12 were concerned with anomalies and diseases of the heart or great vessels and 7 with acute or chronic disease of the pancreas

Congenital Dislocation of Hip

In order to decide whether the changes in the head of the femur and the acetabulum in congenital dislocation of the hip are due to the dislocation or the cause of it, W S SMITH (Columbus) dislocated one hip joint in each of 22 puppies In 6 of the animals the dislocation was reduced at once, but in 16 it was allowed to persist Examination after six months showed that normal development had continued in the 6 control animals, but in each of the 16 animals in which the dislocation had persisted the acetabulum was shallow and the changes in the head and neck of the femur resembled those in congenital dislocation of the hip These findings suggest that the bone and joint changes in congenital dislocation are due to the dislocation and raise the possibility of birth injury as the primary cause of the condition

Obstructive Jaundice in the Newborn

A McDONALD jun (Columbus), pointed out that 60% of cases of obstructive jaundice in the newborn are due to atresia of the bile ducts and 25% to intrahepatic disease especially hepatitis The difficulty in distinguishing between these two causes commonly leads to delay in operation for up to six months until hepatitis has been excluded He has found that early biopsy of the liver through a small incision under local or cyclopropane analgesia will safely provide an accurate diagnosis within one or two months of birth and thus permit early exploration of biliary atresia before the liver is irreversibly damaged.

Exstrophy of the Bladder

O SWENSON (Boston) said that it used to be thought that continence could not be achieved in children with exstrophy of the bladder, and the standard treatment was by transplantation of the ureters Following Sweet s lead Swenson has been repairing the bladder and urethral defects at an early age but has not initially attempted to provide an artificial sphincter Of 16 children treated by early closure within a few weeks of birth, 9 have achieved continence He believes that early closure is better than early transplantation of the ureters followed by delayed closure of the bladder

Splenectomy

B K WISEMAN (Columbus) reviewed the use of splenectomy during the past twenty five years in the treatment of blood dyscrasias in 822 patients, in 745 of whom splenectomy was done with a 4% mortality Accessory spleens were present in 28% No evidence was found of the high incidence of infection which many believe accompanies the surgical treatment of hypersplenism, infection occurred in only 1% of his cases About a quarter of the cases of acquired hæmolytic anæmia did not respond either to operation or to steroids alone or in combination Only a quarter of the patients with thrombocytopenic purpura responded to steroids alone as a primary treatment, but nearly all responded well to the combination of operation and steroid therapy Congenital hæmolytic anæmia responded well to operation unless an accessory spleen was present There were twice as many complications when steroids were used

Operations on the Aorta

R N WATMAN (Columbus) had observed oliguria and sometimes anuria after resection of aortic aneurysms which was associated with a reduction in renal plasma flow of 0–60% In dogs it was found that reduction in renal plasma flow to 0–6 ml per minute from the normal of about 12 ml per minute followed clamping of the aorta, but not when the aorta was dissected out without being clamped After resection of a segment of aorta and replacement by a vena cava graft and release of the clamps the renal plasma flow rose to normal and it remained normal after three months even although the vein graft had now become an aneurysm Slow clamping and slow release of the aorta alone did not reduce renal plasma flow, and bilateral splanchnicectomy protected the animal from the renal effects of rapid release after clamping the aorta By operating under high spinal analgesia they have avoided changes in renal plasma flow in 2 further patients subjected to aortic resection

In one year S R POWERS (Albany, N Y) encountered 4 deaths after resection of aortic aneurysms, which were due largely to distal tubular necrosis By inserting a T shaped cannula into the left renal vein through a lumbar incision it was possible to divert the whole of the renal venous blood to a collecting vessel, urine also was collected, and aortic pressure was recorded When the aorta was clamped, although the renal arterial pressure was maintained the renal blood flow was much reduced and the response to a water load was poor Trimetaphan ('Arfonad') reduced both systemic blood pressure and renal blood flow, but clamping the aorta did not now further reduce renal blood flow, which began to return to normal as the effect of the trimetaphan passed off He concluded that a nervous mechanism is concerned in the reduction of renal blood flow which follows clamping of the aorta and hopes to avoid this by the use of trimetaphan Powers also recommended, however, that in the patient who is fully under the influence of trimetaphan, distal aortic blood flow should be slowly restarted the aortic clamp being replaced by manual compression which is slowly relaxed over a period of about four minutes

Paradoxical hypertension may be a serious and even fatal complication after resection of coarcted aorta In 31 patients W C SEALY (Durham N C) observed an immediate response during the first thirty six hours after operation in 7 but subsequent progress was satisfactory In 14 patients the onset of the response was delayed for more than thirty six hours and it lasted for seven to ten days in patients aged 4–32 years In 6 of these there was severe generalised cramping abdominal pain with vomiting anorexia and gaseous distension In 2 patients the symptoms were so severe that the abdomen was explored and patchy necrosis of the small intestine was found in 1 case the terminal ileum was resected and on histological examination he found thrombosis of the arteries of the intestine and also in the rectus muscle Reduction of the blood pressure by hydrallazine ('Apresoline') relieved the abdominal pain In the delayed type of disturbance the changes are localised to the regions supplied by the aorta distal to the obstruction

F Lewis (St Paul, Minn) had found abdominal pain in 18 out of 80 patients after resection of coarcted aorta, and in 5 it was severe enough to lead to abdominal exploration—1 patient survived extensive gangrene of the small intestine He thought the pain was worst in those who had had the greatest and most sustained fall in blood pressure after operation and wondered whether the changes in the small vessels were similar to those of periarteritis nodosa Sealy thought they were more like those of experimental renal hypertension, he had observed that the onset of symptoms was related to diastolic hypertension

Oxygenators

The difficulties besetting those who are trying to devise satisfactory apparatus for maintaining blood flow when the heart has been shunted were discussed in several papers

C M Maloney (Los Angeles, Calif) had found experimentally that a high rate of blood flow was followed by a large mortality which appeared to be related to the rate of flow through the bubble oxygenator, this mortality could be reduced by using two oxygenators, each with a slow rate of flow, thus allowing the high rate of inflow to the animal to be maintained Although no serious changes were observed in the recipient dog's blood chemistry the mortality rate remained high

C Dennis (Brooklyn, N Y), who had abandoned the bubble oxygenator because of the risk of air embolism, had found that when air is injected into the carotid artery the heart will survive a degree of air embolism which the brain cannot tolerate, such dogs look fine for ten to fourteen hours and then become comatose and die Moreover survival does not exclude the occurrence of air embolism.

G Clowes (Cleveland, Ohio), who uses a membrane-oxygenator, thinks that fibrin, not air, emboli are the probable cause of death, and that these are avoided by his type of apparatus

C W Lillehei (Minneapolis, Minn) has, however, treated 317 patients using a bubble type of oxygenator and thinks that the fundamental problem in cardiac surgery is not the type of oxygenator and by-pass which is used but the methods of dealing with the anatomical lesion The mortality in dogs is high regardless of the type of apparatus used One of the commonest reasons for this may be the priming of the oxygenator with blood from an anæsthetised dog, which may double the dose of anæsthetic to the recipient dog If the adaptors are not streamlined and polished the resulting turbulence may cause fibrin emboli In the helix type of debubbling apparatus which he uses turbulence is avoided Another important factor is the rate of flow, oxygen consumption rises as the flow rate is increased, and the optimum rate appears to be 50–55 ml per kg per minute in patients aged 2–15 years, but these values should be reduced by 20% in adults and increased by 20% in cyanotic disease

Septal Defects

C W Lillehei described his technique of closing ventricular septal defects with an 'Ivalon' plaque and mentioned the value of lung biopsy as a means of assessing the risk of operation in the presence of high pulmonary arterial pressure The number of vessels with intimal hypertrophy in a piece of lung removed through a small intercostal incision gives an indication of the secondary effects of the pulmonary hypertension, such changes may regress after treatment Of 14 patients with only minor vascular disturbance none died after operation, but there were 11 deaths in 14 patients with severe changes These patients died of either cardiac or respiratory failure, and he emphasised that, whereas before operation the left ventricle plays a large part in the maintenance of the circulation through the partially obliterated pulmonary vessels, after operation this depends on the right ventricle alone which in addition now has a long sutured wound in its wall

Only 25 cases of aortico pulmonary septal defect have been described, but D A Cooley (Houston, Texas) encountered his 3 cases in six weeks during 1956 Diagnosis is very difficult because of variation in the clinical signs A catheter may pass into the innominate artery or medium may be seen passing out of the aorta, especially in a retrograde aortogram, a lateral radiograph may then assist in distinguishing this defect from a persistent truncus arteriosus Only 8 patients have ever been operated on and 5 have survived, the first was operated on by Gross in 1948 This anomaly is a wide defect between two vessels and is not a duct, it should therefore be dissected clear and each opening closed by sutures If it is diagnosed before operation hypothermia should be employed, but if it is first discovered only at operation and hypothermia is not being used it is probably wise to stop the operation and reopen the chest later under hypothermia

Coronary Circulation

It has been thought that when the coronary circulation is arrested survival of cardiac muscle is short because of its continuing metabolic demands When the heart is excluded from the circulation for thirty minutes the capillaries become plugged with small clots which stop the blood flow when this is restarted, recovery can be obtained when the coronary blood is first heparinised By removing all the blood from the coronary vessels E F Webb and J D Howard (Jackson, Miss) were able to occlude the coronary circulation experimentally for ninety minutes with resumption of normal function and a resting work-load The dogs did not survive because normal respiration could not be re established.

W H Spencer (Philadelphia, Pa) described a method of perfusing the coronary arteries in order to extend the range of tolerance of hypothermia After clamping the aorta proximal to the arch, blood is injected into the root of the aorta and so perfuses the coronary circulation The heart is subsequently able to maintain a normal range of blood pressure without a latent period of hypotension such as occurs without coronary perfusion

Hypothermia and the Adrenals

The effect of hypothermia on the three phases of adrenal steroid function—secretion, conjugation, and excretion—have been studied by H E Swan (Denver, Colorado) In the uncooled subject there is an early rise in the free blood-corticoid substances followed by a later and smaller rise in the conjugates The urinary content of conjugates rises early during operation, continues to rise after operation, and falls during the next twenty four hours During cooling, which stimulates the adrenal cortex, free corticoids rise in the blood, but once cooling has been achieved no further rise occurs until the patient is warmed when the level of free corticoids rises to that found in uncooled patients The blood-level of conjugates rises slowly during cooling, changes little in the cooled state, and does not rise as the free corticoids do after rewarming The urinary output of corticoid material is delayed and does not rise significantly until after rewarming, renal clearance of creatinine also is depressed during the cooled state Thus in hypothermia not only is the output of free corticoid reduced but conjugation and excretion also are depressed, and the two later phases remain subnormal for some time after rewarming, but all three functions gradually return to normal in the course of a day or so

J D Hardy (Jackson, Miss) has found that some conjugation of adrenal steroids occurs in the hepatectomised dog, and that some other organ is concerned in this aspect of corticoid metabolism but possibly accounts for only a small part of the normal conjugation

Pancreatic Carcinoma

In carcinoma of the pancreas external irradiation is of limited value When 10 μC ^{198}Au was injected experimentally into the head of the pancreas (R J Ireton, Columbus) most of the gold remained in the region of the injection site, but some was found in adjacent lymph nodes, little was excreted, no effects were observed on other organs, and there was no pancreatitis This isotope may therefore be of value in the treatment of carcinoma of the pancreas in man

Pancreatitis

Although 50–75% of patients with pancreatitis have also disease of the biliary tract it is believed that bile does not enter the pancreatic duct system, because of the high secretory pressure in the pancreas D W Elliot (Columbus) cannulated the pancreatic duct and produced localised hæmorrhagic pancreatitis by the injection of 10 ml of bile after forty eight hours of obstruction of the duct Accidental obstruction of the main pancreatic duct showed that despite extensive pancreatic obstruction only the area affected by the bile injection became hæmorrhagic The acute hæmorrhagic process is more rapidly induced, and the animals are more ill when the gall bladder is first filled with pancreatic juice before bile is withdrawn for injection into the pancreas

CENTRAL SURGICAL ASSOCIATION

THE 11th annual meeting of the Central Surgical Association was held on Feb 21–23 at Chicago, Illinois, under the presidency of Dr **ROBERT M ZOLLINGER** (Columbus, Ohio) The 46 papers presented at the meeting will be published in the *Archives of Surgery*

Analysis of Lung Tissue

Spectrographic analysis of lung tissue resected from patients with industrial lung disease has shown the presence of manganese, silicon, thorium, iron, zinc, and silver (in a patient who had used nasal drops for a prolonged period) **R JENSIK** (University of Illinois) in reporting these observations suggested that this method of analysis might be profitably applied to lung tissue which showed no evidence of malignant disease or infection

Colostomy

In order to avoid the fluid losses which follow the establishment of a double barrelled colostomy after resection of an irreducible ileocæcal intussusception, **J A ROONEY** (Loyola University) has devised a T shaped anastomosis About 2 inches of the end of the ileum is denuded of mesentery and is pushed into the lumen of the transverse colon The proximal stump of colon is then brought out as a single barrelled colostomy through a separate incision This allows the small intestine to drain freely into the colon, but there is little loss of intestinal contents from the colostomy

Pancreatitis

Recurrent pancreatitis often improves if any associated disease of the biliary system is relieved **C PUESTOW** (University of Illinois) believes that progression or recurrence of the pancreatitis is related to constriction of the proximal part of the main pancreatic duct When only the tail of the gland is involved local resection is often satisfactory Pancreatitis confined to the head of the gland can be treated by excision with anastomosis of the distal part of the gland to the jejunum, but this carries a fairly high mortality rate He therefore recommends cutting slices off the tail of the gland until the main duct is seen to be dilated, the duct is then slit to open it more widely and the proximal stump of the gland is inserted into the side of a Roux Y limb of jejunum for 2 inches and the wall of jejunum is sewn to the serosa of the pancreas This type of procedure has been employed in 15 patients, 13 of whom subsequently gained weight, were relieved of pain, and passed normal stools Since all these patients had constrictions of the proximal part of the main pancreatic duct of up to 6 cm in length no benefit would have followed division of the sphincter of Oddi, and prolonged drainage or anastomosis of the common bile duct would probably have been of little value

Lumbar Sympathectomy

In order to determine directly at operation the area affected by lumbar sympathectomy **W C RANDALL** (Loyola University) applied wide bands of starch paper to the lower limbs after these had been painted with iodine A very wide variation in anatomical arrangement of the lumbar sympathetic chain was found, preganglionic fibres entering at any level from L1 to L5 Since there is no way of predicting the effects of sympathectomy apart from the sweating test, either this should be done routinely on the operating table or the conventional excision of L2–3 should be extended to L1–5 No evidence of sweating in the opposite limb was found, so it seems unlikely that fibres cross the midline

Carcinoma of Breast

The surgical treatment of 230 patients with carcinoma of the breast between 1946 and 1951 was reviewed by **S P** [illegible] (University of Chicago) Radical mastectomy was employed in 90% of cases with 2 postoperative deaths, 56% survived for five years, but not all without further evidence of the disease These patients did not represent a true sample of the population of the country as a whole

Aganglionic Megacolon

Intestinal obstruction unrelieved by conservative treatment affects only a minority of infants with aganglionic megacolon but in these the mortality rate varies from 25% to 60% **W K SIEBER** (Pittsburgh, Penn) reported 30 such cases in infants under 6 months of age only 6 were females Of 16 less than a month old 7 died, 2 survived without colostomy, and in the remainder colostomy led to rapid improvement Of the 12 older patients, 3 died, and in 2 survival followed colostomy, 3 died of peritonitis, which in 2 cases was due to perforation of the bowel following enemas, 4 died after prolonged ineffectual "medical management," 2 of pseudomembranous colitis, and 1 after colostomy had failed to relieve obstruction when the entire colon was affected by the aganglionic lesion. It is dangerous to delay colostomy proximal to the affected segment, which results in prompt recovery except in the presence of pseudomembranous colitis or severe disturbance of body fluid equilibrium

Arterial Grafting

H B SHUMACKER (Indianapolis, Ind) reviewed the fate of 80 plastic grafts applied to large vessels In only 1 instance was failure due to the graft Nylon filter fabric seems to be suitable for replacement of the distal part of the aortic arch and thoracic and abdominal aorta and the bifurcation, braided nylon grafts do well between the aorta and the iliac and femoral arteries

D E SZILAGYI (Detroit, Mich) examined by serial angiograms and histologically the results of 200 arterial homografts Various grades and types of degenerative change were found in about 20% of the grafts, but there was no evidence of thrombosis attributable to defects of the graft itself Rupture of the graft, with the formation of an aneurysm may be commoner than has been suspected Though there seem to be grounds for preferring plastic grafts to homografts he believes that the life of plastic materials is limited

Portal System and Liver

Percutaneous splenoportography was discussed by **M S DE WEESE** (Ann Arbor, Mich) The procedure was attempted 134 times in 120 patients, with 85% successes 30 ml of 70% 'Urecon' was injected in four seconds, the first film being taken half way through the injection A good shadow of the portal venous system appeared after twenty seconds The procedure was complicated by bleeding in 6 patients, pneumothorax in 3, and subcapsular extravasation of blood in 3 In 9 cases the needle did not enter the spleen Collateral vessels may be shown in portal hypertension and cirrhosis, but not in normal patients Useful information of the state of the portal vein may be obtained A filling defect in the liver was seen in 5 cases of primary hepatic neoplasm, and neoplasms of the body (but not the head) of the pancreas may be shown by venous filling defects This method of investigation should not be used if laparotomy is indicated anyway

W A ALTEMEIER (Cincinnati, Ohio) described 3 examples of cholangioma, a rare type of carcinoma of the intrahepatic bile ducts It progresses slowly over years, sometimes in young subjects, resembling an inflammatory rather than a malignant neoplastic process, ultimately it causes stenosis of the bile ducts, progressive jaundice, and impaired liver function Histological examination usually leads to a diagnosis of sclerosing cholangitis 2 of his patients were repeatedly subjected to operation during several years Though the ultimate prognosis is bad, survival is usually much longer than with other carcinomas of the bile ducts

Lung Function

W E ADAMS (Chicago, Ill) and his group compared the response to exercise of dogs whose lung volumes had been acutely reduced by 75–85% with others in which a similar reduction had been made six or seven years earlier In the first group, the average resting pulmonary arterial pressure was 90% above normal, but in the second group the pressure was only 20% above normal Exercise caused only a [illegible] further increase in pressure in the first group, but an [illegible] increase in the second In both groups of animals the oxygen saturation and systemic blood pressure differed only slightly from normal Although some compensation occurs as more time elapses after pneumonectomy the capacity for response to exercise remains poor clearly the less lung removed the better and lobectomy should be preferred to pneumonectomy

Postoperative Nitrogen Balance

J C PEDEN (St Louis, Mo) described the anabolic effect of 17 α ethyl 17 hydroxy androsterone ('Nilevar') in women after hysterectomy and similar operations They were given 75 g protein and 900 calories daily, by intravenous infusion for four days and by mouth for three days On this inadequate intake the controls remained in negative nitrogen balance throughout the fourteen postoperative days for which they were observed, whereas the patients given the [illegible] remained in positive nitrogen balance, even during the second week when the steroid was not given

Parotid Tumours

O H Beahrs (Rochester, Minn) reviewed all the cases of mixed tumour of the parotid gland seen at the Mayo Clinic between 1907 and 1954, and concluded that any tumour which, after a long period of slow growth, begins to grow more rapidly should be suspected of having become malignant, especially if there is also facial palsy If necessary the diagnosis should be confirmed by biopsy When the facial nerve is already damaged or has to be sacrificed at operation an immediate nerve-graft using the auriculotemporal nerve should be used E S Judd remarked that it might be ten to sixteen months before any restoration of function was evident, but that ultimately the functional result was quite good.

The Œsophagus

F S Cross (Cleveland, Ohio) described the use of cinefluorography in the study of neuromuscular abnormalities in the œsophagus In combination with study of the intraluminar pressure it has been found that such neuromuscular disturbances as segmentation and cardiospasm are not separate entities but degrees of a similar kind of disturbance, and are often seen together Their relation to the formation of diverticula and hiatus hernia was shown in a film

In acquired short œsophagus D B Effler (Cleveland, Ohio) moves the cardio œsophageal junction forwards through an incision dividing the crus and the adjacent portion of the diaphragm, then closes the diaphragm behind the œsophagus so that the cardio œsophageal junction lies below the diaphragm, finally the phrenic nerve is crushed

E R Maurer (Cincinnati, Ohio) pointed out that the size of a hiatus hernia was often not related to the severity of the disturbance it caused, or the complications which are associated with it H C Fisher (Denver, Col) believes that the treatment of œsophagitis is more important than the cure of a hiatus hernia Œsophagitis may respond to a holiday or require gastric resection, but he recommended gastrojejunostomy and vagotomy W E Adams (Chicago, Ill) pointed out that simply crushing the phrenic nerve may give lasting relief to elderly or debilitated patients with hiatus hernia He suggested that in obstructed lesions the œsophagus should be drained above the obstruction by lateral gastro-œsophageal anastomosis, and the stomach below the diaphragm by gastrojejunostomy J K Berman (Indianapolis, Ind) reminded the meeting that good access to the hiatus could be obtained by dividing the left coronary ligament, and that only an abdominal approach to the hiatus allowed an adequate examination of the stomach, duodenum, pancreas, and gall bladder, in which he has found associated lesions in 17% of his cases

R A Mustard (Toronto, Ont) reviewed 381 cases of primary carcinoma of the hypopharynx and œsophagus treated in the Toronto General Hospital in 1937–53 The results of high-voltage irradiation were not good Surgical excision led to a longer survival, but the operative mortality rate was 36% With ^{60}Co, swallowing is often much improved and symptomatic relief is achieved more certainly and readily than with high voltage irradiation or operation The ultimate outlook seems no better He suggested that radical surgery should be reserved for patients in good physical condition with early localised lesions and the remainder treated with ^{60}Co

Reviews of Books

Official History of the Canadian Medical Services, 1939–1945

Vol I *Organization and Campaigns* Edited by W R Feasby, B A, M D, lieutenant colonel, R C A M C, supplementary reserve Ottawa Edmond Cloutier 1956 Pp 566 $5

THIS beautifully produced book appears some months after the second volume, which dealt with clinical and professional aspects (see *Lancet*, 1955, ii, 1373) This one describes the organisation, development, and campaigns of the medical and dental services From a corps consisting in 1939 of 40 medical officers and of other ranks in proportion, the medical services of the three Armed Forces grew into sister-organisations containing 5219 medical officers, 4172 nursing sisters, and 40,112 other ranks and ratings, and more than 2 million casualties passed through their hands The record is as factual as painstaking research could make it, and, like most official histories, it is based mainly on reports submitted by smaller field units to headquarters In such reports events tend to fall into a more orderly and deliberate pattern than they had in reality but even those with no personal memories to revive will find this an exciting record, and to the professional historian and medical administrator—both military and civilian—it will prove an invaluable source of reference and a fund of useful information

Enzyme, Antigen and Virus

A Study of Macromolecular Pattern in Action F Macfarlane Burnet, KT, F R S F R C P, director, Walter and Eliza Hall Institute of Medical Research, Melbourne London Cambridge University Press 1956 Pp 193 18s

IN this fascinating monograph, Sir Macfarlane Burnet has taken three biological phenomena—the formation of adaptive enzymes, the production of specific antibodies, and the multiplication of influenza viruses—and has discussed their basic similarities In each case there is growing evidence that ribonucleic acids are intimately connected with directing the synthesis of new protein and the evidence with regard to tobacco-mosaic virus (which has been published since this monograph was written) is even more direct Burnet's theme, which is most clearly stated in the concluding chapter, is that physico-chemical concepts cannot be expected to have much value in explaining how such highly complex macromolecules are synthesised and that the methods by which the cell transfers information about protein synthesis are best understood in terms of communications theory The nucleic acid is thought of as analogous to the coded instructions which are fed to a computing machine, and Burnet has grave doubts whether orthodox chemical methods will be capable of decoding the instructions

The author has never been deterred from putting forward a hypothesis by the thought that it might be wide of the mark, and the success of his policy has been amply justified by his brilliant prediction of the recent work of Medawar and his colleagues on immunological paralysis If this monograph has the effect of stimulating people to new experiments it will have satisfied its author's purpose Certainly biologists in many fields, and physicists and chemists with an interest in biology, will find this monograph highly provocative

The Care of the Expectant Mother

Josephine Barnes, M A, D M, M R C P, F R C S, F R C O G, assistant obstetrician and gynæcologist, Charing Cross Hospital and Elizabeth Garrett Anderson Hospital London Pitman Medical Publishing Co 1956 Pp 270 30s

THIS book has been written primarily for those whose principal contribution to the maternity services is the conduct of antenatal care

In the first section a brief description of anatomy and physiology is followed by chapters on clinical examination, special investigations, advice to the mother, and preparation for childbirth The last chapter in this section gives very useful information about the maternity services in Britain In the second section the author deals with complications of pregnancy, and in the third describes the general diseases which may complicate pregnancy

Rather more dogmatic teaching would have been of advantage in a book of this scope In particular, more detailed advice might have been given about the types of case which should be referred for hospital confinement or for specialist opinion This work does not pretend to be a textbook of obstetrics, but it will meet a definite need for a short readable guide to those who look after women during the antenatal period

Changes in Body-water Compartments during Growth

BENT FRIIS HANSEN, clinical assistant in the Department of Pediatrics, Rigshospitalet Copenhagen Copenhagen Munksgaard 1956 Pp 68 Cr 25

THIS monograph, which is also available as supplement 110 of *Acta Pædiatrica*, gives the results of the author's observations on 93 infants and children

By supplementing his own results with others that have been reported, he has built up a very complete account of what is known of total body water, and of extracellular and intracellular fluid, throughout fœtal life, infancy, and childhood While intracellular fluid, as a percentage of body weight, stays almost constant, there is a striking fall in extracellular fluid, and it is this change which is mainly responsible for the decline in the proportion of body weight accounted for by body fluid Although these conclusions are familiar to many, it is convenient to have the evidence for them collected in one publication, and this should prove a useful work of reference The text is in English, with summaries in English and Danish

Religious Factors in Mental Illness

WAYNE E OATES London Allen & Unwin 1955 Pp 239 16s

CHAPLAINS to mental hospitals have a difficult task for which as a rule they have had little or no special preparation In this little work the problems they will encounter are described and illustrated from hospital practice, of which the author has had considerable experience both as chaplain and as teacher of pastoral counselling to missionary and other students He gives advice which will enable psychiatrist and clergyman to work helpfully together

New Inventions

AN ADJUSTABLE GUIDE-DIRECTOR FOR TRIFIN NAIL INSERTION

THE insertion of cannulated nails and nail-plate appliances has become standard surgical practice in treatment of fractures about the femoral neck Whilst it is true that experienced surgeons sometimes dispense with mechanical aids in these operations, for the majority one or other of the many guide-wire directors is often helpful

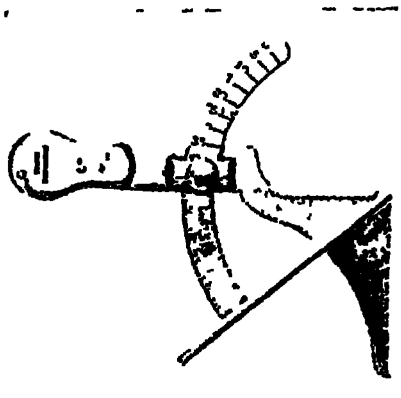

Fig 1—Adjustable guide-wire director, which is sterilised

For Smith-Petersen nail insertion, the technique requires estimation of an angle which will take the guide-wire into position in the head from a selected point on the femoral cortex Insertion of a fixed-angle nail-plate, on the other hand, entails finding a suitable point of entry on the cortex for a nail whose angle of insertion is predetermined in manufacture (130–135°) Where a long low nail technique is favoured for sub-capital fractures, a line from the centre of the head passing just above the calcar femorale determines both the point of entry in the cortex for the nail and its angle of insertion To be of practical value, a guide-wire director should provide this information simply and quickly

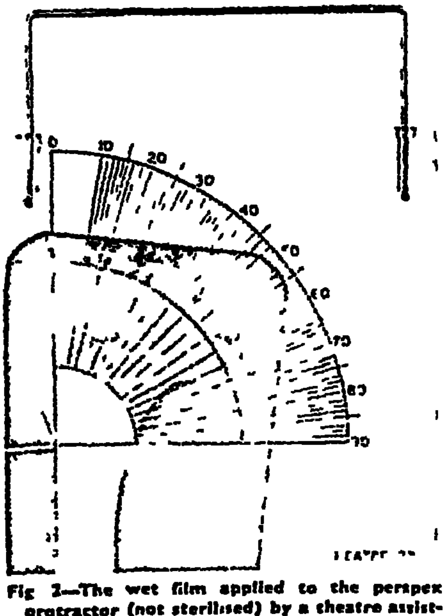

Fig 2—The wet film applied to the perspex protractor (not sterilised) by a theatre assistant slid into proper register and held up to the operator for selection of angle

A protractor type of director, which has proved reliable and simple in use, has come to be adopted in nailing technique in our unit during the past four years

The director is designed on a principle similar to that described by King in 1939 [1] and aims to provide accurate placing of the nail in the anteroposterior radiographic projection, leaving the position in the lateral projection to be estimated by the surgeon Two pieces of equipment are required as illustrated—a metal adjustable guide-wire director (fig 1) and a 'Perspex' sheet protractor The desired angle of nail-insertion from a fixed point on the femur, or the suitable point of entry for a fixed angle nail-plate is determined, after manipulative reduction of the fracture and exposure of the femur, by taking an anteroposterior radiograph with a marker held against the femoral cortex This wet film is applied to the perspex sheet and, by sliding it into register with the protractor (fig 2), the particular angle and point of entry can be chosen and then transferred to the femur by the suitably adjusted guide-wire director As shown in the illustrations, a bradawl marks the selected entry point for ordinary Smith-Petersen nailing For nail-plate and long low nail insertion, the director itself is held against the femur as the marker, and the particular notch on its straight edge is chosen which will carry the appliance into correct position in the femoral head and neck The femoral cortex is drilled at the point of entry in the usual way, the director set to the selected angle, and the guide wire passed with the director held firmly in position against the femur (fig 3) The same technique has also been used for convenient selection of site and direction of cut in performing McMurray osteotomy

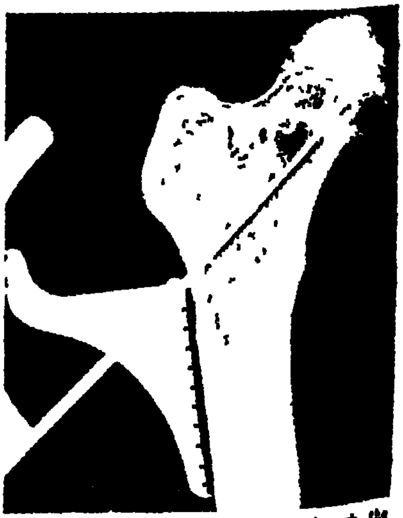

Fig 3—A guide-wire inserted through the director which has been set to the angle indicated and held firmly against the femur

THE LANCET

LONDON SATURDAY, MARCH 16, 1957

Lung Cancer in Women

LUNG cancer is increasing among women, but the tenfold rise in the past forty years has been overshadowed by the far more dramatic change in men. In England and Wales for the years 1911–15 the age-specific death-rate for women was 9 per million living, and by 1951–53 it had risen to 96; in the same time the rate for men had increased from 15 to 569.[1] The changes are most profitably visualised in cohort analyses of the mortality-rates, and CASE[2] has lately emphasised the great value of this method of analysis as a narrative or historical technique. It allows the changing pattern of the recorded mortality to be seen in temporal relation to the changing structure and environment of the population; and knowledge derived from social and medical history can be used to interpret it. Cohort analysis follows the development of some attribute, in this case the rate of dying from lung cancer, in a group of people born within a defined period. Thus, for lung cancer, the age-specific death-rates of women in England and Wales born around the year 1871 was 0.026 per thousand living when the group had reached the age of 50 to 54; but the cohort born around 1901 were subject at the same age to a rate five times as great (0.135). For men, the comparable rates were 0.066 and 1.231—almost a twenty-fold increase. CASE[3] analysed the death-rates for cancer at 21 sites during the period 1911–54 in England and Wales. He found that the male death-rates at ages over 60 were always higher than the female for the sites common to both, and in all but 5 sites the male rate was higher at all ages studied. The death-rate from cancer at all sites in both sexes has fallen between 1911 and 1954; on the other hand, the rate for all sites in men is rising; but, if lung cancer is excluded, the trend, as in women, is downwards, and the mortality-rates for all sites except lung at the age of 50–54 in persons born around 1901 are, for men, 70%, and, for women, 80% of the rates that affected those born thirty years earlier. In women, as in men, the mortality-rates for lung cancer show a steady rise with each succeeding cohort.

The histological pattern of the disease differs in the two sexes. In necropsy material the adenocarcinomas have been reported to be divided almost equally between men and women, with in some cases a slight predominance of men.[4–7] In material obtained by biopsy the reported ratio of men to women has in general been higher, up to 3.3 to 1 and 4.4 to 1 in this country.[8 9] Adenocarcinomas undoubtedly form a higher proportion of all lung tumours in women than in men.[6–12] Because of the varying criteria of classification, it is hard to estimate changes in the pattern of histological types throughout the period of the disease's increase. There is no convincing proof that adenocarcinomas have not increased at all; but there is suggestive evidence that the increase has been least in this type of tumour.[13] For this and other reasons, many people believe that there are two types of lung cancer, exogenous and endogenous in origin. The adenocarcinomas, bronchiolar-cell carcinomas, adenomas, and salivary-gland tumours form the endogenous tumours, which have an equal sex incidence and no connection with known external irritants.[14]

In both men and women, the close connection between tobacco-smoking and lung cancer has been conclusively demonstrated. DOLL and BRADFORD HILL,[8] for instance, found that 37% of 108 women with lung cancer were non-smokers, compared with 55% of their paired controls; 11% of those with lung cancer had been smoking 25 cigarettes or more a day, compared with only 0.9% of the controls. The relationship of smoking to the development of particular histological types of lung cancer has also been investigated.[8 14–17] From a study of 300 patients in Norway, KREYBERG[14] concluded that tobacco-smoking was not an important cause in the development of the adenocarcinoma group of tumours in either men or women. In the U.S.A., WYNDER and his colleagues[17] studied the smoking habits of 105 women with lung cancer and compared them with those of 1304 women with cancer or benign tumours at other sites. Of the 41 with adenocarcinomas 29 were non-smokers; the number expected on the assumption that the smoking habit of these 41 women was the same as that of the patients without lung cancer was 32. On the other hand, only 16 of 41 women with squamous carcinomas were non-smokers, compared with the expected number of 30; and there were 5 non-smokers among the 14 with anaplastic carcinomas, the expected number being 10. A high proportion of adenocarcinomas would be expected in women if this type were not caused by smoking, for fewer women smoke and fewer of those who do smoke heavily. A social survey in this country in 1951 showed that 53% of women did not smoke and only 6% smoked 15 or more a day.[8] In the U.S.A., WYNDER et al. found that about half the women under 50 and most of those over 50 in their control group were non-smokers and that less than 2% of the women over 50 smoked as much as a packet a day. The differences in the mortality-rates for lung cancer in men and women have been used in the past to try to refute the unwelcome conclusion that smoking causes lung cancer. In fact, the pattern of the disease and the smoking habits of women add further support to an already overwhelming case. From an investigation of lung cancer in non-smokers,

DOLL[18] concluded that the proportion of men and women among them was consistent with the hypothesis that in the absence of smoking and exposure to industrial carcinogens the death-rates are equal in the sexes, and HAENSZEL et al,[19] in the U S A, found that the known difference in smoking habits could be expected to lead to an incidence among men approximately four times that in women—which is approximately the present sex-ratio in the mortality statistics of that country

There is some evidence that relatively fewer women than men with lung cancer are seen at hospitals The sex-ratio from death certificates in 1951–53 was 5 9 to 1, and from a necropsy series from eight hospitals in London during 1948–52 it was 4 7 to 1 [7] But the ratios in most series compiled from the records of attendance at or admission to hospitals have been higher In the group reported by DOLL and BRADFORD HILL [8] from several general and special hospitals in 1948–52, the ratio was as high as 13 to 1, and ratios of a similar order have been recorded in thoracic surgical centres, special hospitals, and radiotherapy departments [9 11 12 20 21] In a large series from hospitals in Birmingham [22] during the years 1936–52, the ratio was 7 to 1, and among those treated surgically it was 15 to 1 Differences between the sexes are also seen in the pattern of histological types The proportion of differentiated tumours in necropsy series seems to be much the same in the two sexes,[6 7] but among hospital admissions and attendances [8–10 12] and in surgically treated patients [11 20] not only have there been relatively fewer women but also relatively fewer with differentiated tumours Little has been reported about differences between the sexes in the evolution and modes of presentation of the disease The pattern of survival in untreated patients, however, has been said to be broadly similar in men and women [23], and it seems likely that proportionately fewer women have been operated on in the past In the series of 910 patients described by NICHOLSON and his colleagues [12] there were 70 women, and only 5 (7%) had a resection "with any hope of cure" A significantly better prognosis after operation has, however, been recorded in women BIGNALL and MOON [11] found two-year and five-year survival-rates of 65% and 57% among 41 women, compared with 46% and 31% among 412 men, more of the women had undifferentiated tumours, but fewer had enlarged mediastinal nodes

Lung cancer in women has in general received less attention than the disease in men It has been estimated [24] that the male death-rate in England and Wales may increase from its present level of 687 per million to 1350 per million before it stabilises, and the incidence of lung cancer in women will also increase It may rise more rapidly than it has done in the past, since the fashion of heavy cigarette-smoking evolved more recently in women than in men and its effects may only now be starting to influence the national death-rates from this partly preventable disease

Effects of Fœtal Anoxia

THE adjustment from intra-uterine to extra-uterine life is one of the most important and difficult changes in any individual's life Fortunately, for most of us it is a physiological process, but for too many it still carries a mortality and morbidity of its own While perinatal mortality remains challengingly high, it naturally receives more attention than perinatal morbidity, but it should not be forgotten that many infants who survive the perinatal period do so only with a severe handicap The recent work on perinatal mortality by BOUND and his colleagues [1] has shown that even when accurate clinical data are matched with careful pathological examinations, it is hard to correlate clinical cause with pathological effect This is not altogether surprising in view of the infinitely variable complications of late pregnancy and labour, the poor definition of many neonatal syndromes, and the limitations of even expert pathological examination of stillbirth and neonatal deaths

If this is true of severe lesions which cause death and which can be studied in recent necropsy material it shows how formidable is the task of delineating the influence of birth hazards on surviving infants Over a century ago, LITTLE [2] suggested that cerebral anoxia caused spastic diplegia, and much work has been done since then Methodological difficulties have made much of this evidence hard to interpret and there are many contradictions Many workers have favoured the retrospective inquiry, in which groups of abnormal children were selected and their birth histories investigated It has been shown [3–7] without doubt that many children with cerebral palsy, mental retardation, epilepsy, and behaviour disorders have a history of prematurity, difficult birth, or neonatal anoxia There is a very strong case for blaming trauma or anoxia for the cerebral palsies not due to kernicterus, but it is not so certain that mental retardation is a common sequel of perinatal lesions YANNET,[8] surveying 2500 admissions to a school for the mentally retarded, could attribute only 3% to mechanisms associated with the process of birth Some of the objections to retrospective techniques have been eliminated in a series of studies by LILIENFELD and his colleagues [9–12] They selected a group of abnormal children born between certain dates, and the birth certificates of these children were extracted The next birth certificate relating to a child of the same sex, race, maternal age, and parity was then taken as a control, and the birth history of the abnormal child was then compared with his matched control [9] A highly significant association was demonstrated between complications of pregnancy and labour and the development of cerebral palsy,[10] epilepsy,[11] and mental deficiency [12] There was a lesser association with behaviour [13] and reading disorders, and some association with tics[14] but none with speech difficulties[15] Conditions associated with a sustained intra-uterine hazard, such as pre eclamptic toxæmia or bleeding in late pregnancy, seemed to be a greater threat than short-lived anoxic states or difficult labour

Important as these findings are in assessing the contribution made by perinatal events to the total number of handicapped children, they give little guidance to the doctor who is trying to predict the course of a particular child whose independent existence has been achieved only with difficulty. This guidance can be gained only from longitudinal studies of many closely observed pregnancies The pioneer work has not given a definite answer some investigations[16–18] revealed considerable deviations from normal, whereas others[19–22] detected little harm from adverse birth conditions But direct comparison of these results is not altogether justifiable some are based on a study of babies slow to start breathing, others on children born after difficult or long labour, and the assessment of normality is hardly a standardised procedure It is clear, however, that many babies can survive long periods of asphyxia without damage to the nervous system or the intellect—a tribute to the infant's powers of withstanding hypoxia,[23] as well as an encouragement to those who plead for more active resuscitation of the newborn Nevertheless, these results must lack precision because of the many variable factors in normal birth, for example, the clinical state of the newborn infant is only a rough guide to the degree and duration of intra-uterine anoxia Recoverable lesions of nerve-cells cannot be distinguished on clinical grounds from permanent destruction, and independent genetic and cultural influences may affect both the fœtus and the process of birth, giving rise to a spurious causal association

Some, but by no means all, of these difficulties may be lessened by adopting a specific objective measure of the infant's condition at birth as a basis for follow-up studies, and the most readily accepted measure is that of oxygen saturation The normal infant achieves an arterial oxygen saturation of over 90% in the first hour of life, and infants who fail to do so may be considered hypoxic It is of obvious interest to relate their later development to the degree of hypoxia at birth, and three such inquiries[24–26] are in progress It is still too early to say whether they will solve the main problem it seems unlikely that they will, since hypoxia at birth is only one of many variables that may affect development, and it may be a sign only of some underlying disorder which may itself vary considerably in its effect on the infant Thus, anoxia at birth may be due to a temporary interruption of fœtal oxygen supply caused by traction on the umbilical cord, or to a mild depression of the infant's respiratory centre by anæsthesia given to the mother again, it may be the result of severe intracranial hæmorrhage or long-continued exposure to an unfavourable uterine environment, as in pre-eclamptic toxæmia Clearly, all these factors cannot be eliminated in planning and controlling such investigations APGAR and her associates[25] found no correlation between the blood-oxygen levels measured in the first three hours after birth and intelligence as tested in early childhood PENNOYER's work[26] has not reached the stage of providing follow-up data, but *there are some* interesting preliminary findings Anæsthesia other than pudendal block and analgesia if given in moderate doses within four hours of delivery, produced *some* reduction in oxygen saturation The cord oxygen saturation was low in 54 complicated deliveries, and these babies and those subjected *to* prenatal complications both had difficulty in reaching normal saturations within one hour It does seem, therefore, that oxygen saturation in the first hour of life is some guide to perinatal hazard This extends the work of MONTGOMERY et al[27] and ROOTH and SJÖSTEDT,[28] who have examined the influence of cæsarean section on the oxygen saturation of cord blood and shown that cæsarean section, especially if performed under inhalation anæsthesia, leads to hypoxia Whether the measurement of oxygen saturation is a better measure of the clinical state of the baby than careful observation, duration of apnœa,[29] *or measurements of* respiratory volume,[30] is difficult to say, but it is less vulnerable to subjective impressions and, with accurate techniques, it is reproducible

The last words on the prognosis of fœtal anoxia remain to be written Until then, it is essential to remember that reduction of *mortality is not* the only goal physiological parturition must be *the* aim and the infant must not, without very good reason, be exposed to anything that may conceivably be harmful While awaiting the results of further investigations, we must do everything possible *to help infants to recover* from an abnormal birth and adapt themselves successfully to extra-uterine life

Remuneration

THE members of the Royal Commission to inquire into the remuneration of doctors and dentists were made known on Tuesday The chairman is SIR HARRY PILKINGTON and the names of the other members appear on p 583 The terms of reference were announced earlier[31]

At a meeting with the PRIME MINISTER this week, the joint chairmen of the Negotiating Committee, SIR RUSSELL BRAIN and DR TALBOT ROGERS, discussed the possibility of an interim adjustment, to which MR MACMILLAN had earlier referred A statement issued afterwards on behalf of the Negotiating Committee said that there had been no fundamental change in the situation The PRIME MINISTER had now agreed to make a statement at some later but as yet indefinite date about the nature of the adjustment MR MACMILLAN later told the House *that* the pay of junior hospital medical and dental staff, up to *and* including senior registrar, would be increased by 10% from April 1, and as reported on p 583, MR THORNEYCROFT announced plans for raising the salaries of university staff

OSTEITIS IN THE NEWBORN

THE fall in neonatal mortality has concentrated attention on infection as the most important single cause of death after the first week of life Particular concern has been expressed about hæmatogenous osteitis, for although the mortality of this condition is now low, the results of inadequate treatment can be crippling Dennison[1] pointed out that it is hard to compare the results achieved in different series nevertheless it is encouraging to note the improvement on previously published results recorded in the paper by Professor Boyes and his colleagues on p 544 Their frank discussion of failures is particularly informative

Most instances of osteitis in the newborn are caused by the obtrusive staphylococcus, and the invasion of the antibiotic-resistant organism has been nowhere more threatening than in the care of newborn infants, particularly those born in hospital The osteitis is a local manifestation of a generalised infection and its clinical course varies considerably It can be quite mild, and has usually been so described in the past, or it can be rapidly fatal Any bone may be affected, and the region of the hip is a common site and one where the effects can be serious Bones developed in membrane are often among those attacked, and many infections involve the maxilla, in these flat bones where the resistance is low the infection is specially virulent

It seems that the severe form is a new and violent manifestation of an old disease, and, since it is an eminently treatable condition, its early diagnosis is of prime importance Any swelling of the soft tissues, any signs of irritability in a child that is being moved or washed, any suggestion of immobility, or any generalised infection associated with an apparently superficial lesion, must raise the suspicion of this severe underlying condition Tenderness over bone is the sign to look for One important lesson is that soft tissue infections are not at all common in the newborn and all suspicious lesions should be treated as arising in bone until the contrary is proved As in the now rare osteomyelitis of older children, the radiographs are slow to reflect the bone changes and they never give the full picture of the havoc, since much non-opaque cartilage may be destroyed

The first line of treatment is vigorous, uninterrupted, and long continued chemotherapy Penicillin and streptomycin are given at once, and the sensitivities of the organism determined if possible Once the infection is well under control, treatment by injection can give way to an appropriate drug by mouth One of the important points that has emerged is that treatment must be continued for a long time The average length of treatment in the series described by Professor Boyes and his colleagues was five to six weeks, and experience has tended to lengthen rather than shorten the course Pus should be aspirated, and here again it is necessary to needle repeatedly and at the slightest provocation Even the keenest supporters of bone drilling for infection could hardly say that it was the treatment of choice in patients of this age Sequestra should be removed and it is important to think of loose teeth as sequestra

Even with the sustained care and interest which Professor Boyes and his associates devoted to their treatment, a quarter of the children were left with a crippling deformity of one or more joints The analysis of these failures discloses some valuable facts Apart from late diagnosis, the two big causes of failure were inadequate length of treatment and failure to aspirate pus Where the infection was in the neighbourhood of the hip, the results were really bad in spite of long-continued chemotherapy and orthopædic treatment, the destruction was severe, except in one case diagnosed early

How can this damage be prevented? Doctors and midwives should always be on the lookout for "minor sepsis," and be ready to seek a second opinion if they have any doubts whether it is truly minor And they should urge mothers not to hesitate to seek advice for such conditions When it comes to antibiotic treatment, it must be assumed that the organism is hardy if not immune, and large doses must be given for a long time But all rests on early diagnosis, and early diagnosis depends on suspecting osteitis when the bone changes are still slight

NERVE-GAS POISONING

THE nerve gases are organic phosphorus compounds which powerfully and irreversibly inhibit cholinesterase They were first synthesised in Germany in the 1930s by Schrader, who was searching for new insecticides Except for their greater potency, they have the same pharmacological and toxicological action as the rapidly expanding group of organic phosphorus insecticides[1]

The nerve gases can enter the body through the lungs, the intact skin, or the eye In the conscious animal a lethal dose causes muscular fasciculation, followed by incoordination, convulsions, prostration, gasping respirations, "air hunger," engorgement of veins, and often precipitate micturition and defæcation The animal falls unconscious and stops breathing, the heart slows, cardiac output and blood pressure fall, and the pupils may contract (miosis is an early sign if the eyes are directly exposed) Finally, the skin capillaries collapse and the heart stops beating In all species so far studied the general post-mortem appearance is that of asphyxia Respiration can fail because of paralysis of the respiratory centre (the most important factor), bronchoconstriction or paralysis of the muscles of respiration by neuromuscular block The degree of bronchospasm and muscular paralysis depend on the compound used and the species poisoned Breathing is made even harder by the profuse secretion of mucus from the bronchial glands and the abolition of the cough reflex

Normally, acetylcholine is hydrolysed almost as soon as it is released, but when cholinesterase is destroyed, acetylcholine accumulates where it is produced The symptoms of poisoning are the result of excessive parasympathetic stimulation (muscarine action), neuromuscular block (nicotine action), and paralysis of the vital centres in the brain stem (central action) The parasympathetic and central effects of acetylcholine are prevented and reversed by atropine, which is the most effective antidote to poisoning by organic phosphorus compounds Large doses must be given early and must be continued, more atropine being given as indicated by bradycardia or miosis Cullumbine[2] emphasises that there should be no hesitation in giving more doses if the patient's condition demands it, since acetylcholine is continually being released But atropine does nothing to combat the nicotine action, so that peripheral neuromuscular paralysis persists Since death is due to respiratory failure caused by central paralysis, bronchoconstriction, or neuromuscular block, the efficacy of atropine in different species depends on the relative importance of these three mechanisms In man and the monkey, respiratory failure is central in origin and the response to atropine is good Certain oximes and hydroxamic acids can reactivate inhibited cholinesterase They and hasten the destruction of absorbed nerve gas but they promise to be useful adjuncts to atropine, but the compounds of this type so far investigated are too toxic for general use and the search for better ones continues

[1] See annotation *Lancet* Feb 2 1957 p 260

[2] Cullumbine H *J R Army med Cps*, 1957 103 [illegible]

Early treatment is vital, and it has been recommended that, in war, the individual Serviceman should be responsible for his own treatment. But the first signs and symptoms of poisoning are vague, and it is hard to know when atropine is really needed. The dose to be self administered must therefore be a compromise between one of therapeutic value in nerve-gas poisoning and one which can be given safely to a normal person. Trials under different conditions have shown that 2 mg. (gr. $^1/_{30}$) of atropine sulphate intramuscularly is a reasonable dose.

In severe poisoning, positive-pressure artificial respiration will support the action of atropine by improving oxygenation of the tissues (in asphyxia atropine is a less effective stimulant of the respiratory centre). Positive pressure is needed to overcome the resistance due to bronchospasm, but ordinary manual methods of artificial respiration should form part of first-aid, preferably by the Holger-Nielson (arm-lift/back-pressure) method. A manually operated positive pressure respirator, such as a bellows resuscitator or a mask-to-mask device, is being considered for field use.

TETANUS AFTER OPERATION

THE power of tetanus to strike a hospital with sudden ferocity is again evident in recent events at the North Staffordshire Royal Infirmary, Stoke-on-Trent. Tetanus attacked 5 patients lately operated on in the main surgical block at the infirmary: 2 have died and the latest information about the others is that they are "unchanged and still very ill." All operations at the infirmary have been suspended for the time being and work is being transferred to other hospitals in the group. The source of the infection has not yet been identified. Those concerned will have in mind particularly previous disasters in which tetanus has been attributed to dust entering the operating-theatre,[1] to infected hair used in repairing plaster walls,[2] to infected talc powder,[2] to catgut,[3] and to the use of other imperfectly sterilised materials.[4 5]

EPIDEMIC VERTIGO

IN the study of the more benign diseases of short duration, the general practitioner has advantages over his colleagues in hospital; and this is well illustrated by what has been written about epidemic vertigo. In 1949 Walford[6] described a case of vertigo during an epidemic of influenza. In the following year Meulengracht[7] pointed out that what was thought to be an example of drug toxicity was in all probability a disease known in Denmark as "vertigo epidemica," or "neurolabyrinthitis epidemica." Subsequently Rogers[8] described 3 further patients, and Stewart[9] suggested that the cause might be a virus labyrinthitis. Since then rather more than 50 cases have been reported from general practice in different parts of the country. Further attention has lately been drawn to this condition by Charters,[10] who, in a paper from Kenya, discusses 13 cases that he has seen in the eight years between 1947 and 1955.

The clinical picture of epidemic vertigo seems to be reasonably clear. The patient has a sudden attack of severe vertigo accompanied by nausea and vomiting. The vertigo may last from one day to two weeks and then gradually ease (being brought on at this stage by movements of the head) until it subsides entirely. There is, however, considerable variation in the recorded duration of vertigo, Worster Drought[11] stating that it gradually improves in six to nine weeks, rarely lasting as long as twelve months. The vertigo is accompanied by nystagmus, and sometimes by headache, generalised pains, and slight fever for a day or two at the onset. Tinnitus and deafness, though not the rule, do affect a small proportion of patients. Leishman[12] mentions that 3 of his patients had diplopia, and this symptom was present in 2 of Dalsgaard-Neilsen's series[13] of 21 cases in Copenhagen and in 2 of Charters's patients. The disease may affect either sex and the patient may be of any age, the youngest described being three years old; but it is generally mild in children and is more common as well as more severe in those over twenty.

There has been much discussion about the ætiological agent, its infectivity, and the site of damage, but many more facts are needed. Cases have occurred during epidemics of influenza, but vertigo as a direct result of influenza is usually accompanied by deafness. Moreover, epidemic vertigo may appear at any time of year, and often it is unassociated with pyrexia. It is tempting, therefore, to consider this disease as an infection by a distinctive virus, though Alcock[14] takes the view that there are several different causes. In Charters's series of 13 cases, 10 appeared between May, 1954, and August 1955. There was no special predilection for any particular month, and the cases were widely scattered throughout Kenya. He supports Burrowes's view[15] that the disease may be spread by carriers. This point might be settled by wider study of the condition in general practice and a comparison with other diseases prevalent at the time.

In most infections the labyrinth and cochlea are often involved together. Since tinnitus and deafness are relatively uncommon in epidemic vertigo, it seems unlikely that the end-organ itself is affected (virus infections very rarely attack this structure).

The electro-encephalogram showed a "mild abnormality" in 6 of Dalsgaard-Neilsen's 13 cases, but it was normal in the remaining 7. Moreover, the cerebrospinal fluid has been normal almost every time it has been examined. It also seems unlikely that a brain-stem encephalitis would confine itself to the labyrinthine nuclei, with occasional involvement of the cochlear nucleus and even more rare damage to one oculomotor nucleus; what is more, it would have to do so without causing any general upset in most patients (Dalsgaard Neilsen mentions slight changes in reflexes or sensibility). On the other hand, it is hard to explain in any other way the involvement of the oculomotor nerves if this condition is to be attributed to one cause.

Embryologically and phylogenetically, the vestibular nerve and ganglion develop before the cochlea, and this may be a factor in the localisation of the damage. If so, then epidemic vertigo would be one variety of vestibular neuronitis. The disease does, in fact, show many points of resemblance to vestibular neuronitis as described by Dix and Hallpike,[16] in particular the age distribution, the onset associated with a febrile illness, and the localisation to the vestibular apparatus. It differs from vestibular neuronitis in its short course and in the possible involvement of the auditory apparatus. These differences, however, may well be differences of pathology rather than of anatomy. Charters suggests that the condition is a ganglionitis and that spread might be occasionally expected from Scarpa's ganglion to the cochlear nerve. This is an interesting postulate, and, while the analogy he draws with herpes zoster cannot be pushed very far, it is not an unreasonable hypothesis.

Aschan and Stahle[17] have lately described 10 cases of vestibular neuritis (neuronitis) some of which might well be epidemic vertigo. By means of nystagmography and the more usual investigations, they support the view that the lesion is in the peripheral vestibular neurone or the brain stem nuclei. Although nystagmography could not be generally applied, it would be interesting to refer more patients thought to have epidemic vertigo for caloric tests, audiometry, electro encephalography, and possibly galvanic tests at an early stage of their illness, for none of these investigations is very burdensome to the patient.

Treatment must clearly be empirical. The distressing vertigo can usually be relieved by rest in bed for a short period, and simple sedatives are usually sufficient until the trouble subsides. Nevertheless, the disease remains a challenge, and more energetic efforts to explain what it is may yield results which have a bearing on virus infections as a whole.

PULMONARY FUNCTION AFTER PNEUMONECTOMY

AFTER pneumonectomy without thoracoplasty it might reasonably be expected that the volume of the remaining lung would increase, and that the consequent over inflation would impair respiratory activity. In fact, lung volume does tend to increase, but there is often little change in the various criteria of respiratory efficacy. Thus, Cournand et al[1] made a survey of ventilation perfusion relationships and gas exchange in 16 patients after pneumonectomy, and found that distension did not inevitably follow, even with some degree of over inflation and hyperventilation, the respiratory performance was in the lower part of the normal range. Friend,[2] who examined 15 men before and after pneumonectomy, found evidence that the remaining lung increased in volume, but that the over-inflation did not progress for more than three months. Over-inflation of itself had "no demonstrable adverse effect on ventilation", Friend also demonstrated post-operative respiratory insufficiency only in those patients who had chronic bronchitis, and he concluded that the maximum breathing capacity test could predict post operative dyspnœa.

McIlroy and Bates[3] examined 10 men, aged between 39 and 63, who had had a pneumonectomy from eight months to eight years before, all operations had been done, without thoracoplasty, for carcinoma of the bronchus. They measured intraœsophageal pressure (as an index of intrathoracic pressure), so that lung compliance and flow resistance could be estimated, and the pulmonary diffusing capacity (by the carbon-monoxide method) both at rest and during exercise on a treadmill. In 6 patients with little evidence of over inflation of the lungs the results were what would be expected with a halving of the tissue available for respiration. In about half the patients, the compliance was less than that expected for one normal lung (i e, there was a smaller increase in volume than normal for a given increase in pressure) and in most cases the compliance decreased more rapidly than normal as the lung volume increased. The respiratory work on exercise was greater than normal even when the lung was not over inflated, and much greater when it was over inflated, this might be expected since the ventilation of one lung alone is about double that of two lungs, for a given exercise rate, hence there would be a bigger resistive pressure component across the lung for a given rate of air flow than there would be if there were two lungs to share the flow, with the correspondingly lower flow resistance offered by two sets of airways in parallel instead of one. This was in accordance with the finding of a mean inspiratory resistance greater than normal in all the patients. In 3 patients there was over inflation (evidenced by a low intraœsophageal pressure and grossly increased functional residual volume), but normal gas diffusion was maintained. 1 patient, [illegible] years after operation, had a much over inflated lung but normal end-expiratory pressure, indicating a loss of elastic recoil, and considerable impairment of gas diffusion with a ventilation higher than normal for a given oxygen uptake, he could be considered to have emphysema.

Thus, the absence of one lung may result in very little change in the function of the other, but, since only one lung is left to bear the respiratory burden, there is a tendency to over inflation. A low intrathoracic pressure leads not only to over inflation but also to a fall in compliance. The tendency then is for the lung to lose elasticity, with a consequent rise in intrathoracic pressure and functional residual capacity, and a relative fall in diffusing capacity, gas distribution, however, is little deranged, differentiating the condition from classical emphysema secondary to long standing bronchitis.

McIlroy and Bates began their investigation with three questions in mind. The first was whether over inflation led to dyspnœa through changes in the mechanical properties of the lungs, they presume that postoperative dyspnœa is due to the necessary over ventilation of the remaining lung, and that over inflation accentuates the dyspnœa by a further reduction in compliance. The second question was whether the diffusing capacity was lowered, and if so what were the results, they found it was generally half the value in normal people, and this reduction means a greater ventilation for a given oxygen uptake. The relation between over inflation and emphysema constituted the third question, and the results suggested a clear distinction between these two conditions, for "over inflation results in an increased lung volume with a low intrathoracic pressure level and normal gas diffusion. Emphysema, on the other hand, is characterised by an increased lung volume with a normal intrathoracic pressure level and impaired diffusion."

POLIOMYELITIS VACCINE

THE colour change in a few vials of poliomyelitis vaccine during storage[1] has been traced to contamination. In a letter to medical officers of health, Sir John Charles, chief medical officer of the Ministry of Health, says that faulty containers were to blame and the contaminant was a non pathogenic *Pseudomonas fluorescens*. Repeated sterility tests on the remainder of the batch have been negative. After incubation at 37°C, 25°C, and room temperature, normally coloured vaccine showed no discoloration. It has therefore been decided to proceed with the issue of this batch of vaccine.

THE Q J M

IN 1907, at the first meeting of the Association of Physicians of Great Britain and Ireland, plans were made to establish a medical journal to publish "papers which, though scientifically important, were not suitable for the Journals, nor for the clinical or pathological societies." The name first chosen was *Archives of Medicine*, but there must have been objections to this title, for it was soon changed to one now familiar wherever medical journals are read—*The Quarterly Journal of Medicine*. The energy of William Osler, for 12 years its editor, gave the new venture a flying start, and in the succeeding 50 years of vigorous life it has been ably served by a distinguished line of editors. We congratulate them and all who have helped them to attain this anniversary. To mark the occasion an attractive jubilee number has just been published, and in an opening article Sir Russell Brain recounts the history of the association and the journal and mentions some of the memorable names connected with them.

OPERATION SESAME*

EDWARD S STERN
M.A, M D Camb, M R C.P, D P M
MEDICAL SUPERINTENDENT,
CENTRAL MENTAL HOSPITAL, HATTON

ON June 5, 1956, I opened the last closed ward at Hatton, so that now any of our 1380 patients is free to walk out of the place if he wants to do so This could not have been achieved without the cooperation of the staff, and many physical difficulties have had to be surmounted

In the first place we have no main gates (our visiting anæsthetist and his car saw to that eleven years ago) there is not even a porter at the place where the gates were We are surrounded by farmland with ordinary hedges and fences and twenty open gateways in them We are close to a canal and a main railway line Our buildings are mostly a century old, with wards opening out of each other and many other antiquated inconveniences We have overcrowding of over 40% That we are short of nurses is, I believe, immaterial, for our staff turnover is low, and that is far more important Our patients are unselected, and include short order cases under sections 20 and 21 of the Lunacy Act, 1890, for we act as our own observation wards

THE FIRST STEPS

It is fitting that we should be among the earliest to unlock our wards, for Hatton was the first asylum in which no patient was ever put under mechanical restraint It was opened in 1852 during an enlightened period Unfortunately the beginning of the 20th century was a period of recession in psychiatry, marked by a flight from the patient into the study of pathology, psychobiology, biophysics, biophysiology, biometry, biochemistry, binovular twins, even the binomial theorem, and other byways of the physical sciences

When I was a junior medical officer two events made me resolve to open the doors of the hospitals The first was when my old chief, the late Dr A O'Neill, told me with compunction that, in the twenty-five years that Napsbury Hospital, St Albans, had been opened, more patients had been placed under observation and more wards had been locked The second was when I found that a patient of mine had recovered after many years in the hospital I proposed his release, only to be told by the senior nurse that he had been so long detained that he was now institutionalised and unfit ever to leave I am glad to say that I did secure his discharge and I believe that he did well But what a reflection on the mental hospital it was, that prolonged stay there should unfit a man for normal life I resolved that I would, if ever I had the chance, reverse the process, open more wards, and make mental treatment fit the patient to live the good life outside

When I arrived at Hatton as medical superintendent in 1942, I found 3 of 14 female and 4 of 11 male wards open Throughout the hospital were many peremptory notices "Lock this Door" As an immediate first step I unlocked the door between two open male wards The staff did not know that this was only the thin end of the wedge, but I now literally had my foot in the door

Other reforms were started Chronic sick were collected together in one ward, and epileptics in another The use of suicidal caution cards was discontinued We have never regretted this as the pink tickets have died our patients have lived

STEADY PROGRESS

But until the Appointed Day I was able to open only one more ward On that day, however, the dual medical and lay control, which had been a peculiarity of Hatton for 13 years, was ended The result was electric In a single day there was an immense rise in morale which has continued ever since The progress in unlocking wards is shown in the table

Sometimes there was a long pause between openings This was because the staff could not accept it unless patients who were regarded as likely runaways were transferred to closed wards The advent of such ill-reputed people to wards where the new freedom was already feared naturally further delayed their own opening But even the most conservatively minded staff eventually wanted to be in the swim and asked if their wards, too, could not be opened It became U to have one's ward unlocked and non-U to keep it closed Occasionally a change in charge-nurse led to the rapid opening of a ward

Each ward is shown by a figure giving the number of patients at the time of opening New wards are shown in italics

The disturbed wards were not always the last to be opened It often proved more difficult to liberate senile and demented patients who are inclined to wander and get lost Indeed the only serious accident we have had was with one of these

Since 1942 the total number of wards has been increased by 3, and these have been open from the beginning Altogether the 28 wards have over 100 open and unguarded doors

HOW WE DID IT

The male and female sections of our main building can largely be shut off by locking central doors, and on the women's side we opened the wards at first behind these closed doors It was, in fact, possible to walk out of the building without a key, but only if one had an intimate knowledge of the design of the women's side —a knowledge that even many nurses did not possess A few months later we quietly opened the section doors quietly because we did not wish to upset the doubters among the staff—we knew that the patients could take it and would be all right On the men's side we opened

be epidemic vertigo By means of nystagmography and the more usual investigations, they support the view that the lesion is in the peripheral vestibular neurone or the brain stem nuclei Although nystagmography could not be generally applied, it would be interesting to refer more patients thought to have epidemic vertigo for caloric tests, audiometry, electro-encephalography, and possibly galvanic tests at an early stage of their illness, for none of these investigations is very burdensome to the patient

---

* Based on a paper read at the annual general meeting of the Royal Medico-Psychological Association on July 19, 1956

Treatment must clearly be empirical The distressing vertigo can usually be relieved by rest in bed for a short period, and simple sedatives are usually sufficient until the trouble subsides Nevertheless, the disease remains a challenge, and more energetic efforts to explain what it is may yield results which have a bearing on virus infections as a whole

PULMONARY FUNCTION AFTER PNEUMONECTOMY

AFTER pneumonectomy without thoracoplasty it might reasonably be expected that the volume of the remaining lung would increase, and that the consequent over inflation would impair respiratory activity In fact, lung volume does tend to increase, but there is often little change in the various criteria of respiratory efficacy Thus, Cournand et al[1] made a survey of ventilation perfusion relationships and gas exchange in 16 patients after pneumonectomy, and found that distension did not inevitably follow, even with some degree of over inflation and hyperventilation, the respiratory performance was in the lower part of the normal range Friend,[2] who examined 15 men before and after pneumonectomy, found evidence that the remaining lung increased in volume, but that the over-inflation did not progress for more than three months Over inflation of itself had "no demonstrable adverse effect on ventilation", Friend also demonstrated post-operative respiratory insufficiency only in those patients who had chronic bronchitis, and he concluded that the maximum breathing capacity test could predict post operative dyspnœa

McIlroy and Bates[3] examined 10 men, aged between 39 and 63, who had had a pneumonectomy from eight months to eight years before, all operations had been done, without thoracoplasty, for carcinoma of the bronchus They measured intraœsophageal pressure (as an index of intrathoracic pressure), so that lung compliance and flow resistance could be estimated, and the pulmonary diffusing capacity (by the carbon-monoxide method) both at rest and during exercise on a treadmill In 6 patients with little evidence of over inflation of the lungs the results were what would be expected with a halving of the tissue available for respiration In about half the patients, the compliance was less than that expected for one normal lung (i e, there was a smaller increase in volume than normal for a given increase in pressure) and in most cases the compliance decreased more rapidly than normal as the lung volume increased The respiratory work on exercise was greater than normal even when the lung was not over inflated, and much greater when it was over inflated, this might be expected since *the ventilation of one lung* alone is about double that of two lungs, for a given exercise rate, hence there would be a bigger resistive pressure component across the lung for a given rate of air flow than there would be if there were two lungs to share the flow, with the correspondingly lower flow-resistance offered by two sets of airways in parallel instead of one This was in accordance with the finding of a mean inspiratory resistance greater than normal in all the patients In 3 patients there was over inflation (evidenced by a low intraœsophageal pressure and grossly increased functional residual volume), by normal gas diffusion was maintained 1 patient, [illegible] years after operation, had a much over inflated lung but normal end-expiratory pressure, indicating a loss of elastic recoil, and considerable impairment of gas diffusion with a ventilation higher than normal for a given oxygen uptake, he could be considered to have emphysema

Thus, the absence of one lung may result in very little change in the function of the other, but, since only one lung is left to bear the respiratory burden, there is a tendency to over inflation A low intrathoracic pressure leads not only to over inflation but also to a fall in compliance The tendency then is for the lung to lose elasticity, with a consequent rise in intrathoracic pressure and functional residual capacity, and a relative fall in diffusing capacity, gas distribution, however, is little deranged, differentiating the condition from classical emphysema secondary to long standing bronchitis

Each ward is shown by a figure giving the number of patients at the time of opening New wards are shown in italics

The disturbed wards were not always the last to be opened It often proved more difficult to liberate senile and demented patients who are inclined to wander and get lost Indeed the only serious accident we have had was with one of these

Since 1942 the total number of wards has been increased by 3, and these have been open from the beginning Altogether the 28 wards have over 100 open and unguarded doors

HOW WE DID IT

The male and female sections of our main building can largely be shut off by locking central doors, and on the women's side we opened the wards at first behind these closed doors It was, in fact, possible to walk out of the building without a key, but only if one had an intimate knowledge of the design of the women's side —a knowledge that even many nurses did not possess A few months later we quietly opened the section doors quietly because we did not wish to upset the doubters among the staff—we knew that the patients could take it and would be all right On the men's side we opened

be epidemic vertigo By means of nystagmography and the more usual investigations, they support the view that the lesion is in the peripheral vestibular neurone or the brain stem nuclei Although nystagmography could not be generally applied, it would be interesting to refer more patients thought to have epidemic vertigo for caloric tests, audiometry, electro encephalography, and possibly galvanic tests at an early stage of their illness, for none of these investigations is very burdensome to the patient

---

* Based on a paper read at the annual general meeting of the Royal Medico Psychological Association on July 19, 1956

Treatment must clearly be empirical The distressing vertigo can usually be relieved by rest in bed for a short period, and simple sedatives are usually sufficient until the trouble subsides Nevertheless, the disease remains a challenge, and more energetic efforts to explain what it is may yield results which have a bearing on virus infections as a whole

PULMONARY FUNCTION AFTER PNEUMONECTOMY

AFTER pneumonectomy without thoracoplasty it might reasonably be expected that the volume of the remaining lung would increase, and that the consequent over-inflation would impair respiratory activity In fact, lung volume does tend to increase, but there is often little change in the various criteria of respiratory efficacy Thus, Cournand et al[1] made a survey of ventilation-perfusion relationships and gas exchange in 16 patients after pneumonectomy, and found that distension did not inevitably follow, even with some degree of over-inflation and hyperventilation, the respiratory performance was in the lower part of the normal range Friend,[2] who examined 15 men before and after pneumonectomy, found evidence that the remaining lung increased in volume, but that the over-inflation did not progress for more than three months Over-inflation of itself had "no demonstrable adverse effect on ventilation", Friend also demonstrated postoperative respiratory insufficiency only in those patients who had chronic bronchitis, and he concluded that the maximum breathing capacity test could predict postoperative dyspnœa

McIlroy and Bates[3] examined 10 men, aged between 39 and 63, who had had a pneumonectomy from eight months to eight years before, all operations had been done, without thoracoplasty, for carcinoma of the bronchus They measured intracesophageal pressure (as an index of intrathoracic pressure), so that lung compliance and flow resistance could be estimated, and the pulmonary diffusing capacity (by the carbon-monoxide method) both at rest and during exercise on a treadmill In 6 patients with little evidence of over inflation of the lungs the results were what would be expected with a halving of the tissue available for respiration In about half the patients, the compliance was less than that expected for one normal lung (i e, there was a smaller increase in volume than normal for a given increase in pressure) and in most cases the compliance decreased more rapidly than normal as the lung volume increased The respiratory work on exercise was greater than normal even when the lung was not over-inflated, and much greater when it was over inflated, this might be expected since the ventilation of one lung alone is about double that of two lungs, for a given exercise rate, hence there would be a bigger resistive pressure component across the lung for a given rate of air flow than there would be if there were two lungs to share the flow, with the correspondingly lower flow resistance offered by two sets of airways in parallel instead of one This was in accordance with the finding of a mean inspiratory resistance greater than normal in all the patients In 3 patients there was over-inflation (evidenced by a low intracesophageal pressure and grossly increased functional residual volume), normal gas diffusion was maintained 1 patient, e years after operation, had a much over inflated l but normal end-expiratory pressure, indicating a lo elastic recoil, and considerable impairment of g diffusion with a ventilation higher than normal for a given oxygen uptake, he could be considered to have emphysema

Thus, the absence of one lung may-result in very little change in the function of the other, but, since only o lung is left to bear the respiratory burden, there is a tendency to over inflation A low intrathoracic pressure leads not only to over-inflation but also to a fall in compliance The tendency then is for the lung to lose elasticity, with a consequent rise in intrathoracic pressure and functional residual capacity, and a relative fall in diffusing capacity, gas distribution, however, is little deranged, differentiating the condition from classical emphysema secondary to long standing bronchitis

McIlroy and Bates began their investigation with three questions in mind The first was whether over inflation led to dyspnœa through changes in the mechanical pròperties of the lungs, they presume that postoperative dyspnœa is due to the necessary over ventilation of the remaining lung, and that over inflation accentuates the dyspnœa by a further reduction in compliance The second question was whether the diffusing capacity was lowered, and if so what were the results, they found it was generally half the value in normal people, and this reduction means a greater ventilation for a given oxygen uptake The relation between over-inflation and emphysema constituted the third question, and the results suggested a clear distinction between these two conditions, for "over inflation results in an increased lung volume with a low intrathoracic pressure level and normal gas diffusion Emphysema, on the other hand, is characterised by an increased lung volume with a normal intrathoracic pressure level and impaired diffusion"

POLIOMYELITIS VACCINE

THE colour change in a few vials of poliomyelitis vaccine during storage[1] has been traced to contamination In a letter to medical officers of health, Sir John Charles, chief medical officer of the Ministry of Health, says that faulty containers were to blame and the contaminant was a non pathogenic *Pseudomonas fluorescens* Repeat sterility tests on the remainder of the batch have been negative After incubation at 37°C, 25°C, and room temperature, normally coloured vaccine showed no discoloration It has therefore been decided to proceed with the issue of this batch of vaccine

THE Q J M

IN 1907, at the first meeting of the Association of Physicians of Great Britain and Ireland, plans were made to establish a medical journal to publish "papers which, though scientifically important, were not suitable for the Journals, nor for the clinical or pathological societies" The name first chosen was *Archives of Medicine*, but there must have been objections to that title, for it was soon changed to one now familiar wherever medical journals are read—*The Quarterly Journal of Medicine* The energy of William Osler, for 12 years its editor, gave the new venture a flying start, and in the succeeding 50 years of vigorous life it has been ably served by a distinguished line of editors We congratulate them and all who have helped them to attain this anniversary To mark the occasion an attractive jubilee number has just been published, and in an opening article Sir Russell Brain recounts the history of the association and the journal and mentions some of the memorable names connected with them

OPERATION SESAME*

EDWARD S STERN
MA, MD Camb, MRCP, DPM
MEDICAL SUPERINTENDENT,
CENTRAL MENTAL HOSPITAL, HATTON

ON June 5, 1956, I opened the last closed ward at Hatton, so that now any of our 1380 patients is free to walk out of the place if he wants to do so This could not have been achieved without the cooperation of the staff, and many physical difficulties have had to be surmounted

In the first place we have no main gates (our visiting anæsthetist and his car saw to that eleven years ago) there is not even a porter at the place where the gates were We are surrounded by farmland with ordinary hedges and fences and twenty open gateways in them We are close to a canal and a main railway line Our buildings are mostly a century old, with wards opening out of each other and many other antiquated inconveniences We have overcrowding of over 40% That we are short of nurses is, I believe, immaterial, for our staff turnover is low, and that is far more important Our patients are unselected, and include short order cases under sections 20 and 21 of the Lunacy Act, 1890, for we act as our own observation wards.

THE FIRST STEPS

It is fitting that we should be among the earliest to unlock our wards, for Hatton was the first asylum in which no patient was ever put under mechanical restraint It was opened in 1852 during an enlightened period Unfortunately the beginning of the 20th century was a period of recession in psychiatry, marked by a flight from the patient into the study of pathology, psychobiology, biophysics, biophysiology, biometry, biochemistry, binovular twins, even the binomial theorem, and other byways of the physical sciences

When I was a junior medical officer two events made me resolve to open the doors of the hospitals The first was when my old chief, the late Dr A O'Neill, told me with compunction that, in the twenty-five years that Napsbury Hospital, St Albans, had been opened, more patients had been placed under observation and more wards had been locked The second was when I found that a patient of mine had recovered after many years in the hospital I proposed his release, only to be told by the senior nurse that he had been so long detained that he was now institutionalised and unfit ever to leave I am glad to say that I did secure his discharge and I believe that he did well But what a reflection on the mental hospital it was, that prolonged stay there should unfit a man for normal life I resolved that I would, if ever I had the chance, reverse the process, open more wards, and make mental treatment fit the patient to live the good life outside

When I arrived at Hatton as medical superintendent in 1942, I found 3 of 14 female and 4 of 11 male wards open Throughout the hospital were many peremptory notices "Lock this Door" As an immediate first step I unlocked the door between two open male wards The staff did not know that this was only the thin end of the wedge, but I now literally had my foot in the door

Other reforms were started Chronic sick were collected together in one ward, and epileptics in another The use of suicidal caution cards was discontinued We have never regretted this: as the pink tickets have died our patients have lived

STEADY PROGRESS

But until the Appointed Day I was able to open only one more ward On that day, however, the dual medical and lay control, which had been a peculiarity of Hatton for 13 years, was ended The result was electric In a single day there was an immense rise in morale which has continued ever since The progress in unlocking wards is shown in the table

Sometimes there was a long pause between openings This was because the staff could not accept it unless patients who were regarded as likely runaways were transferred to closed wards The advent of such ill-reputed people to wards where the new freedom was already feared naturally further delayed their own opening But even the most conservatively minded staff eventually wanted to be in the swim and asked if their wards, too, could not be opened It became U to have one's ward unlocked and non-U to keep it closed Occasionally a change in charge-nurse led to the rapid opening of a ward

HOW WE DID IT

The male and female sections of our main building can largely be shut off by locking central doors, and on the women's side we opened the wards at first behind these closed doors It was, in fact, possible to walk out of the building without a key, but only if one had an intimate knowledge of the design of the women's side—a knowledge that even many nurses did not possess A few months later we quietly opened the section doors quietly because we did not wish to upset the doubters among the staff—we knew that the patients could take it and would be all right On the men's side we opened the section door before the wards I think that, on the whole, this was the more difficult method

---

* Based on a paper read at the annual general meeting of the Royal Medico-Psychological Association on July 19, 1956

In 1949 we were so short of women nurses that we stationed a male nurse in our disturbed women's ward by day to quell any possible outbreak of violence The result was unexpected There was no violence, but the patients began to use cosmetics and take a renewed interest in their appearance We discovered that we could improve each side by the introduction of the opposite sex

We have opened the dormitories so that patients can go to bed when they like, and can use the sanitary annexe which is open at night This has done away with the use of chamber-pots, dangerous both as weapons and as a means of spread of intestinal infection The bathrooms are open and we dispense with key-taps But we lock the outer doors of the hospital at night just as in our own homes

I think it important not only to unlock the doors but also to give the appearance of freedom To that end we have opened as many doors into each ward as we safely can, having regard to the danger of falls by old people down steep stairways Since we unlocked our ward garden-gates we are finding that the airing-court is a thing of the past, and this will free land for other purposes The railings which surrounded our cricket field and home paddock have been taken down The latter is now a park

SOME USEFUL PRINCIPLES

In carrying out the operation we found the following principles useful

The patients must be happily occupied Their occupations should be outside the wards, which are used mainly for eating and sleeping, and so regarded by the patient as his home We began occupations on a large scale for chronic disturbed patients in 1945 The resulting improvement, though slow, has been sure and has exceeded all my expectations

Recreations must be provided away from the wards These should generally be of a high class, for if you give the patients only trivial fare you show that you think they have trivial tastes and trivial minds Games and dancing are valuable, especially if they are provided by outside bodies Our constant aim is the resocialisation of the patient for his eventual discharge

The patient must be respected as a person All his complaints and requests, and those of his relatives too, must be considered There must be infinite patience and gentleness in all our dealings with him It may be wondered how we manage with the chronic paranoid individual who is continually trying to escape We have found that the hostility of such people can be worn down by constant kindness After all why should a patient leave the only place where he can always be sure of a kind word and a sympathetic ear?

The patient's clothes should be improved

Holidays and visiting should be encouraged We allow visiting at any time while retaining our regular visiting days

The staff must be continually stimulated and supported, for the mental hospital must be a happy and confident place and opening the doors is a matter of staff confidence

SOME DIFFICULTIES

The sort of opposition we met from the nurses was "The patients will escape What shall I do?", and finally, "Who will be responsible?" Our answer was, "Don't worry, nurse, we'll be responsible" In fact, when a ward is first unlocked, nothing at all usually happens Perhaps a patient finds the door is unlatched and hastily closes it again, the next patient to discover this draws the sister's attention to the irregularity The patients have to be encouraged to take a stroll outside For they are threatened with the loss of the security of chronic psychosis

Shortages of staff sometimes led nurses to give keys to patients Whenever the matron discovered this, she would say "Nurse, I have just found a patient with your key, so you cannot tell me if the ward is locked or not You had better leave it open, for then at least you will know" Now we find that those who were most doubtful at first are as enthusiastic as the rest of us Of course we all had some anxiety then, and I sometimes feared that Operation Sesame might become Operation Pandora But we never opened a ward until the staff was ready for it, and always left the final decision to the sister or charge-nurse

At first we had more escapes after we opened our wards, now we have fewer They did not give rise to such anxiety as formerly, for they were no longer antisocial To prevent them we need a new technique in mental nursing, known absconders must be constantly occupied and interested This is not as formidable as it sounds, for they soon learn to engage themselves contentedly at all times We have not had any notable trouble with local residents or police, nor do the patients pester staff or visitors at the hospital

ADVANTAGES

On the other hand, the advantages have been abundant and increasing, and no-one at Hatton would care to return to the days of imprisonment for mental illness The whole staff-patient relationship is transformed Nurses are no longer regarded as turnkeys On the day that we opened the admission ward for men, the duly authorised officer said, "This is the best thing you have ever done Now you have made it easy for me to persuade patients to enter the mental hospital"

Seclusion of patients in a locked room, formerly common, has almost ceased and is practically confined to patients who have just been admitted Violence, resistance, and hostility have virtually disappeared, and so has forced feeding Wards that were previously disturbed have become the most popular with staff, for they are full of recovering chronic patients many of whom have already been discharged and are known to be doing well at home

Patients have learnt to be independent and responsible Their behaviour with strangers or at a party is exemplary—i e, better than that of the general public

At the end of June our Hospital League of Friends gave a garden party Patients decided for themselves whether they wished to go and then went out and enjoyed themselves without supervision At the end of the day they all returned to their wards at the right time No nurses were on point or supervisory duty and this freed them so that they could give their time to helping the halt, the lame, and the blind round the gardens But all that is the usual thing for us

They are out of the wards so much that overcrowding is less serious But we have had to provide more open garden space and seats, as well as a comfortable library where patients can read or write quietly

The strain of nursing has been less since patients have been removed from the wards for periods of the day When they were massed together in a locked room it was common for fights and window smashing to occur, especially in bad weather To return to closed wards would require more nurses than we have

But the open door system does not mean merely undoing locks It means the provision of interests and re education for the patient, respect for his dignity as a person, and friendliness to him in all his needs

Public Health

ATMOSPHERIC POLLUTION, TEMPERATURE INVERSION, AND DEATHS FROM BRONCHITIS

LLYWELYN ROBERTS
M.D. Lond., M.R.C.P., D.P.H.
MEDICAL OFFICER OF HEALTH, SHEFFIELD

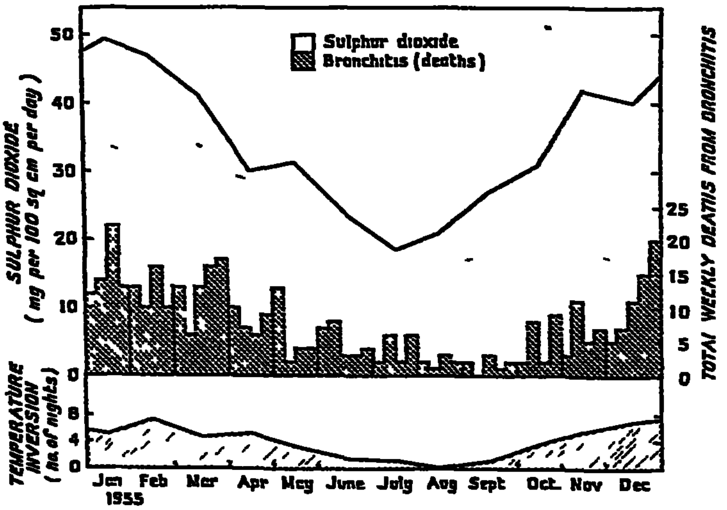
J. W. BATEY
D.P.A.
SUPERINTENDENT SMOKE INSPECTOR, SHEFFIELD

It is common knowledge that the number of deaths from bronchitis tends to rise when the weather is cold and foggy, and it has often been assumed that there is a direct association between the mortality and the climatic conditions. Looking for a more precise association, we have found (see graph) similar trends in

(1) The sulphur-dioxide content of the atmosphere;
(2) The number of days showing "temperature inversion"; and
(3) The number of deaths recorded as being caused by bronchitis.

In the graph, the figure for sulphur dioxide was a monthly total of the readings of thirteen gauges placed in different parts of the city.

An "inversion" was recorded on any night when the minimum temperature (in Weston Park, half a mile from the centre of the city) was at least 5°F lower at ground level than it was four feet above the ground, provided that the cloud cover was less than half during most of the night and the wind not more than force two on the Beaufort scale.



Graph showing total sulphur-dioxide readings, temperature inversion, and deaths from bronchitis in Sheffield, 1955.

The number of deaths was obtained from the list of registered deaths reaching the public-health department.

One could expect an increase of sulphur dioxide in the air in winter because of the increased amount of fuel burnt. It may, however, be true that this increased amount of sulphur dioxide produced is concentrated at ground level on days when there is temperature inversion, because there is then less dispersion of the gases. There are more such days in winter.

Mr J. Barwick, F.R.MET.S., A.M.A., supplied the meteorological data.

Points of View

A STUDY OF WAKE

AN APPROACH TO THE PROBLEMS OF INSOMNIA

W. V. CRUDEN
M.B. Lond.
GENERAL PRACTITIONER, HOVE

SLEEP and wake are the alternating modes of life, but how differently we view them. We assume that "sleep is a temporary cessation of the waking state" (Carter 1955) and study its cause and nature. To study the cause and nature of wake seems foreign to our nature, for we do not find the word "wake" in the index of any textbook. Yet surely arousal is the most spectacular phenomenon in life.

The reason for this prejudice is obvious but not generally recognised. We must be awake to study any problem including that of sleep-wake. It is therefore only natural to take wake for granted and to argue from wake to sleep. But in the same way we must be on the Earth to study any problem including the allied night-day problem, and it was only natural to take the Earth for granted and to argue from Earth to Sun. But that was pre-Copernican error, and science has proved that we must alter our egocentric ideas and argue from Sun to Earth. Is there any justification for thinking that our assumptions over sleep and wake are also erroneous, and that we should change our ideas on this problem and assume that "wake is a temporary cessation of the sleeping state"? Such a change of view is not a mere playing with words. It is a fundamental reorientation of thought and seems to have been under consideration by some students of the subject (Jefferson 1954, Kahn 1916, Wright et al. 1952a).

Sleep as Basic State of Life

If we study objectively the relation of wake and sleep we must first note that life begins in an inert fœtal state that may well be termed "sleep," and that the embryo seems incapable of arousal in its early life. Barcroft's (1946) experiments, however, have shown that in later fœtal life anoxic and tactile stimuli can rouse the embryo while "asleep," so that temporarily it "will wake to activity." But fœtal life is a sleeping life and it is amazing that the fœtus continues its sleep even during labour unless aroused by threatened asphyxia. (Freud [1933] stated that, in adult life, when we try to go to sleep "we try to bring about quite similar conditions to intrauterine life.")

At birth the baby awakes for a short time but, when anoxic and tactile threats have been removed, reverts to sleep. Unlike the fœtus it is now no longer nourished by a kind of perpetual drip-feed through the umbilical vein and it will starve if it sleeps perpetually. It is accordingly awakened at regular intervals by hunger, but as soon as it has fed it is asleep again. (This need for regular feeds remains the fundamental cause for waking throughout life.) At a slightly later age the young baby can also be temporarily aroused by pain, noise, and light but sleep again recurs when these stimuli cease. Like the fœtus the very young baby lives mostly a sleeping life.

The pattern so far, therefore, is quite plain. Sleep is the original and basic state of life. At first it is continuous, but, as development proceeds, this perpetual sleep may be interrupted temporarily by an increasing number of causes which we may term "arousal stimuli."

Nevertheless, throughout this fœtal and very early baby life of sleep, wake is but a briefly temporary cessation of the sleeping state We certainly could not say that the sleep of this period was a temporary cessation of the waking state

But what of the later stages of life ? As development proceeds, this clear-cut pattern alters profoundly We find in the growing baby that the polyphasic waking episodes are prolonged In the young child they gradually merge together into a triphasic and then a biphasic pattern, and finally, with the abolition of the afternoon nap, there is one long monophasic wake period With growing age this increases until the waking hours (sixteen or more) exceed the hours of sleep (eight or less) This long daily vigil continues for many years, but with increasing age there is a gradual return to the baby pattern The afternoon nap of "forty winks" (usually after food) is the first sign of the return of biphasic wake, and in old age triphasic and polyphasic modes are found In extreme senility there is sometimes a return to the almost perpetual sleep of the fœtus, and it may be that the arousal stimuli disappear from life in the reverse order of their appearance

Wake Maintainers

Can we fit this changing picture into the simple pattern mentioned above ? Yes, it seems that we can It is most significant that, as the young baby grows, the period of wakefulness begins to persist after the waking stimulus has apparently been withdrawn For instance, instead of falling asleep immediately after its feed, it will remain awake for a time, interested in a bright light or coloured object or playing with its hands We must therefore postulate the emergence of "wake maintainers" which continue the alert reaction after the arousal stimuli have ceased—cf Kleitman's (1939a) "wakefulness of choice"

These wake maintainers take the form of investigation of, and play with, the environment And their brief and rudimentary origins in the young baby gradually enlarge with age as the awareness of the environment widens, until the broad horizons of adult perception claim the long monophasic period of wake As age increases, however, this zest for investigation and play lessens until, in the apathy of senility, wake maintainers may disappear almost completely Throughout life wake maintainers are less evident in the more vegetative members of society (such as the Fat Boy of Pickwick), and more evident in the more active

Development of Sleep-wake Relationship

Three phases in the development of the sleep-wake relationship may therefore be recognised (1) undisturbed sleep (in the early fœtus), (2) sleep briefly disturbed by arousal stimuli (in the later fœtus and the very young baby), and (3) sleep increasingly disturbed by arousal stimuli supplemented by wake maintainers But, although wakefulness lengthens with the growing need for alertness and diminishes with the diminuendo of old age, sleep is always our perpetual background and is "there" whenever the cause of wake disappears, just as the analogous state of nakedness is "there" whenever we undress Even in adult life wake is still a temporary cessation of the basic sleeping state The acceptance of this view of sleep should be of fundamental help in agrypnophobia

How does wake cease ? Initially wake ceases when the arousal stimulus is removed, witness the infant's relapse into sleep after feeding or having a wet nappie changed (Illingworth 1953) But when wake maintainers supplement the arousal stimuli, what then ? The dominant waking urge may either be abolished by satisfaction, like hunger by food, libido by coitus, and labour by delivery, or fade away through fatigue or adaptation In either case drowsiness and sleep recur

Of course wake maintenance may be suppressed by circumstances If, for instance, we are trapped in the inescapable boredom of a dull lecture or sermon, the removal of the possibility of any kind of purposive activity leads to drowsiness and sleep (Compare the sleep occurring in volunteers submerged in body temperature water, in the experiments of the National Institutes of Health in the U S A) (*British Medical Journal* 1956) The picture is therefore always one of sleep disturbed by a waking agent and automatically recurring when this is removed How similar to its physiological counterpart where the relaxed muscle of the nerve muscle preparation (Wright et al 1952b) contracts with stimulation and relaxes when the stimulus is removed—a picture in miniature of the sleep wake life and of the levator palpebræ superioris muscle in particular

If wake is a temporary disturbance of the basic state of sleep (and it seems that we must accept this unorthodox view), there is no "cause" for sleep but only cause for wake And what is this cause ? We have enumerated the arousal stimuli, tactile and anoxic threats, hunger, pain, noise, and light, in this order of appearance In addition, "exogenous" training (where the parent wakes the infant for excretion, &c) and later "autogenous" training (where the individual trains himself to awake, often with such an aid as an alarm clock) should be added to complete the list of arousal stimuli Why do all these stimuli cause arousal whereas other types of stimuli do not ? Is there any single factor common to the former which is absent from the latter ? Yes, it seems that arousal stimuli all partake of a "threat to well being" which can only be met by the alert reaction, whereas the non-waking stimuli and sleep associated states are devoid of this threat We may cite hunger (not satiety), nightmare (not idyllic dream), arousing shake (not rocking cradle), the smell of burning (not the scent of flowers), bugle (not lullaby), work to be done (not task completed) It is this affective nocuous and therefore prepotent (Wright et al 1952c) element which is required to disturb the placid equilibrium of sleep Perhaps this is the subconscious reason for calling the instrument that awakes us the "alarm" clock Threats below threshold level presumably cause disturbed sleep (sleep movements, sleep noises, dreams, and modification of the sleeping electro-encephalogram) If they reach threshold level they produce the extreme disturbance of wake, the speed of arousal being proportional to the degree of threat The threat of a very loud noise will cause almost instantaneous arousal, whereas minor threats (Kleitman 1939b) whose summation causes our ordinary morning awaking (daylight, minor sounds, hunger-pains, bladder distension, and training) produce a more gradual arousal It is obvious that when wake maintainers contain a large element of threat, as in anxiety, they will prolong the alert reaction in the unwanted wakefulness of insomnia, for which psychotherapy, religion, and relaxing techniques are more rational treatments than is the use of depressive drugs for blocking the pathways to the arousal centres (Arduini and Arduini 1954)

Because they contain this element of threat arousal stimuli are a form of stress I am therefore tempted to suggest that arousal corresponds to Selye's (1954) "alarm reaction," the ensuing period of wake to his stage of "resistance," and the final drowsy fatigue to his stage of "exhaustion," but perhaps this is oversimplifying the sleep wake problem But there is certainly some evidence to suggest that corticotrophin may play a part in waking Polley (1956)

In arousal the placid unconsciousness of sleep is disturbed by nocuous afferent impulses into a conscious awareness of the challenge which the arousal stimulus contains. The first stage of arousal is the introduction of the conscious state by the "open-sesame" of the threat element in the stimulus. But, according to Magoun (1953), modality is unrecognised in the arousal centres, and the second stage therefore is the conscious (cortical) activity which recognises the modality of the arousal stimulus and orients it in time and space. In this connection three observations in the phenomena of awaking may be noted.

(1) Possibly the purposeless athetoid movements of its early stages may be due to the opening of the thalamo cortical circuits by the removal of the suppressor bands (Wright et al. 1952d).

(2) Certainly the mental confusion, fantasy, or hallucination described by Grotjahn (1932) shows the gradualness of waking awareness.

(3) The quasipurposive movements of closing the eyes (often with a frown) after their first brief opening, and of grimaces of displeasure and turning over in bed, all may be connected with the nocuous nature of the arousal stimulus.

Complete awakening leads to action designed to deal with the arousal stimulus, after which wakefulness may continue with pleasurable affect.

Conclusion

The orthodox approach to the sleep-wake problem is due to an obvious (but generally unrecognised) prejudice—i.e., the subject can only be studied when we are awake. If we clear our minds of this prejudice and look at the problem objectively, it appears that sleep is the initial basic mode of life. Wake is a temporary disturbance of the sleeping state. The cause of wake lies in an increasing variety of arousal stimuli which all have the nature of a threat to well being and are therefore forms of stress. The lengthening duration of wake with age is due to the emergence in early life of wake maintainers which "tag on" after the arousal stimuli have ceased. Whenever the arousal stimuli and wake maintainers disappear, the temporary disturbance of the sleeping state ceases.

This conclusion provides a firm foundation for the further study of the physiology and pathology of wake. It entirely reorients the problem of insomnia, the secret of which lies not in the study of sleep but in that of wake (especially the wake maintainers). In particular the acceptance of this basic view of sleep should be of fundamental help to sufferers from agrypnophobia, and the "threat" nature of arousal underlines the importance of anxiety in the maintenance of unwanted wake.

The importance of insomnia and dyssomnia in the production of unhappiness and ill health cannot be exaggerated. It is along the lines described above that we shall reach a solution of the problem.

I am indebted to the late Prof. Samson Wright for helpful criticism.

Parliament

Taxation and Public Expenditure

THE burden of taxation which this country carries and its pressure on the professional classes was one of the main themes of the debate in the House of Lords on March 6. It was recognised that if taxation was to be eased it could only be done by a reduction in public expenditure, and this led several noble Lords to a reconsideration of our social services.

Indeed if we were to achieve any big saving in domestic expenditure we must, Lord BALFOUR OF INCHRYE maintained, do "some basic re-thinking." He readily agreed that the Welfare State must continue to safeguard citizens against such unavoidable hazards as sickness and old age. But he believed that we must throw over the idea which had crept upon us that a Government could do better for the citizen and could spend better for the citizen than a citizen could do for himself if he were released from the present rapacious tax system. The practical application of a revolt against the Government as the spending agent for the citizen would be no subsidised rents for four-figure incomes, no food subsidies, and no free health-service benefits for those who could afford to pay for their own doctors. Against this could be set a level of personal taxation which would allow a man to order his affairs as he wished, to order his own housing, to feed his own family, to doctor as he wished and to educate his children as he wished.

The EARL OF CROMER suggested that the Welfare State was designed against the background of the past but had to be paid for at the cost of the present. Too much of the cost of the Welfare State was devoted to relieving wage-earners of what unhappily they could not afford twenty five years ago, but today in general happily could afford. It was absurd and unrealistic to expend too much of our energies trying to mitigate the hardships of the past. We needed them all to overcome the problems of the present, of which undoubtedly the paramount one was our economic survival, and he reminded noble Lords that of the total Government expenditure of £6000 million a third was on the Welfare State. If a man was working his wages should be at a level to provide him with a decent standard of living. Such funds as the nation could make available for welfare should be devoted primarily to the care of those who could not care for themselves, and to protect those whom society could not look after in the normal sense. Lord Cromer could see no justification in this day and age for large-scale largesse to the population as a whole—such as, for example, family allowances. He suggested that the Welfare-State costs might be divided into two categories: the first covering those items which the normal Christian morality demanded of the State—such as National Assistance and the like—which should be left as a charge against the Budget as at present. The second category, covering other items of the Welfare State, might come under an entirely separate social-security budget which would not have recourse to the general Exchequer, but be financed by National Insurance contributions and by part of the proceeds of purchase tax or a special sales tax. This scheme would have the merit of disillusioning those who believed that they were getting something free, and would produce an awareness of the truth of the situation, which was that the Welfare State had to be paid for, not by someone else, but by every working member of the community.

A less drastic reform, put forward by Lord MOYNIHAN, was for some relief from taxation for people who saved to send their children to schools outside the State system of education, or who chose to go to their own private doctor. Why should not a citizen spend a little of the money he might have in having just a little more than the State would give him? But in doing that, why should he be forced to pay for his medicines, whereas other people who did not take the trouble got it all free? These two were surely blatant attempts at bringing the standard of the people down to a level, rather than trying to raise it.

In replying for the Government VISCOUNT HAILSHAM showed a demure pre-budget reticence which happily

Nevertheless, throughout this fœtal and very early baby life of sleep, wake is but a briefly temporary cessation of the sleeping state We certainly could not say that the sleep of this period was a temporary cessation of the waking state

But what of the later stages of life ? As development proceeds, this clear-cut pattern alters profoundly We find in the growing baby that the polyphasic waking episodes are prolonged In the young child they gradually merge together into a triphasic and then a biphasic pattern, and finally, with the abolition of the afternoon nap, there is one long monophasic wake period With growing age this increases until the waking hours (sixteen or more) exceed the hours of sleep (eight or less) This long daily vigil continues for many years, but with increasing age there is a gradual return to the baby pattern The afternoon nap of "forty winks" (usually after food) is the first sign of the return of biphasic wake, and in old age triphasic and polyphasic modes are found In extreme senility there is sometimes a return to the almost perpetual sleep of the fœtus, and it may be that the arousal stimuli disappear from life in the reverse order of their appearance

Wake Maintainers

Can we fit this changing picture into the simple pattern mentioned above ? Yes, it seems that we can It is most significant that, as the young baby grows, the period of wakefulness begins to persist after the waking stimulus has apparently been withdrawn For instance, instead of falling asleep immediately after its feed, it will remain awake for a time, interested in a bright light or coloured object or playing with its hands We must therefore postulate the emergence of "wake maintainers" which continue the alert reaction after the arousal stimuli have ceased—cf Kleitman's (1939a) "wakefulness of choice"

These wake maintainers take the form of investigation of, and play with, the environment And their brief and rudimentary origins in the young baby gradually enlarge with age as the awareness of the environment widens, until the broad horizons of adult perception claim the long monophasic period of wake As age increases, however, this zest for investigation and play lessens until, in the apathy of senility, wake maintainers may disappear almost completely Throughout life wake maintainers are less evident in the more vegetative members of society (such as the Fat Boy of Pickwick), and more evident in the more active

Development of Sleep-wake Relationship

Three phases in the development of the sleep-wake relationship may therefore be recognised (1) undisturbed sleep (in the early fœtus), (2) sleep briefly disturbed by arousal stimuli (in the later fœtus and the very young baby), and (3) sleep increasingly disturbed by arousal stimuli supplemented by wake maintainers But, although wakefulness lengthens with the growing need for alertness and diminishes with the diminuendo of old age, sleep is always our perpetual background and is "there" whenever the cause of wake disappears, just as the analogous state of nakedness is "there" whenever we undress Even in adult life wake is still a temporary cessation of the basic sleeping state The acceptance of this view of sleep should be of fundamental help in agrypnophobia

How does wake cease ? Initially wake ceases when the arousal stimulus is removed, witness the infant's relapse into sleep after feeding or having a wet nappie changed (Illingworth 1953) But when wake maintainers supplement the arousal stimuli, what then ? The dominant waking urge may either be abolished by satisfaction, like hunger by food, libido by coitus, and labour by delivery, or fade away through fatigue or adaptation In either case drowsiness and sleep recur

Of course wake-maintenance may be suppressed by circumstances If, for instance, we are trapped in the inescapable boredom of a dull lecture or sermon, the removal of the possibility of any kind of purposive activity leads to drowsiness and sleep. (Compare the sleep occurring in volunteers submerged in body temperature water, in the experiments of the National Institutes of Health in the U S A) (*British Medical Journal* 1956) The picture is therefore always one of sleep disturbed by a waking agent and automatically recurring when this is removed How similar to its physiological counterpart where the relaxed muscle of the nerve-muscle preparation (Wright et al 1952b) contracts with stimulation and relaxes when the stimulus is removed—a picture in miniature of the sleep wake life and of the levator palpebræ superioris muscle in particular

If wake is a temporary disturbance of the basic state of sleep (and it seems that we must accept this unorthodox view), there is no "cause" for sleep but only cause for wake And what is this cause ? We have enumerated the arousal stimuli, tactile and anoxic threats, hunger, pain, noise, and light, in this order of appearance In addition, "exogenous" training (where the parent wakes the infant for excretion, &c) and later "autogenous" training (where the individual trains himself to awake, often with such an aid as an alarm-clock) should be added to complete the list of arousal stimuli Why do all these stimuli cause arousal whereas other types of stimuli do not ? Is there any single factor common to the former which is absent from the latter ? Yes, it seems that arousal stimuli all partake of a "threat to well being" which can only be met by the alert reaction, whereas the non-waking stimuli and sleep-associated states are devoid of this threat We may cite hunger (not satiety), nightmare (not idyllic dream), arousing shake (not rocking cradle), the smell of burning (not the scent of flowers), bugle (not lullaby), work to be done (not task completed) It is this affective nocuous and therefore prepotent (Wright et al 1952c) element which is required to disturb the placid equilibrium of sleep Perhaps this is the subconscious reason for calling the instrument that awakes us the "alarm" clock Threats below threshold level presumably cause disturbed sleep (sleep movements, sleep noises, dreams, and modification of the sleeping electro encephalogram) If they reach threshold level they produce the extreme disturbance of wake, the speed of arousal being proportional to the degree of threat The threat of a very loud noise will cause almost instantaneous arousal, whereas minor threats (Kleitman 1939b) whose summation causes our ordinary morning awaking (daylight, minor sounds, hunger pains, bladder distension, and training) produce a more gradual arousal It is obvious that when wake maintainers contain a large element of threat, as in anxiety, they will prolong the alert reaction in the unwanted wakefulness of insomnia, for which psychotherapy, religion, and relaxing techniques are more rational treatments than is the use of depressive drugs for blocking the pathways to the arousal centres (Arduini and Arduini 1954)

Because they contain this element of threat arousal stimuli are a form of stress I am therefore tempted to suggest that arousal corresponds to Selye's (1954) "alarm reaction," the ensuing period of wake to his stage of "resistance," and the final drowsy fatigue to his stage of "exhaustion," but perhaps this is oversimplifying the sleep wake problem But there is certainly some evidence to suggest that corticotrophin may play a part in waking Polley (1956)

In arousal the placid unconsciousness of sleep is disturbed by nocuous afferent impulses into a conscious awareness of the challenge which the arousal stimulus contains The first stage of arousal is the introduction of the conscious state by the "open-sesame" of the threat element in the stimulus But, according to Magoun (1953), modality is unrecognised in the arousal centres, and the second stage therefore is the conscious (cortical) activity which recognises the modality of the arousal stimulus and orients it in time and space , In this connection three observations in the phenomena of awaking may be noted

(1) Possibly *the purposeless athetoid movements of its* early stages may be due to the opening of the thalamo cortical circuits by the removal of the suppressor bands (Wright et al 1952d)

(2) Certainly the mental confusion, fantasy, or hallucination described by Grotjahn (1932) shows the gradualness of waking awareness

(3) The quasipurposive movements of closing the eyes (often with a frown) after their first brief opening, and of grimaces of displeasure and turning over in bed, all may be connected with the nocuous nature of the arousal stimulus

Complete awakening leads to action designed to deal with the arousal stimulus, after which wakefulness may continue with pleasurable affect

Conclusion

The orthodox approach to the sleep-wake problem is due to an obvious (but generally unrecognised) prejudice —i e , the subject can only be studied when we are awake If we clear our minds of this prejudice and look at the problem objectively, it appears that sleep is the initial basic mode of life Wake is a temporary disturbance of the sleeping state The cause of wake lies in an increasing variety of arousal stimuli which all have the nature of a threat to well-being and are therefore forms of stress The lengthening duration of wake with age is due to the emergence in early life of wake maintainers which "tag on" after the arousal stimuli have ceased Whenever the arousal stimuli and wake maintainers disappear, the temporary disturbance of the sleeping state ceases

This conclusion provides a firm foundation for the further study of the physiology and pathology of wake It entirely reorients the problem of insomnia, the secret of which lies not in the study of sleep but in that of wake (especially the wake maintainers) In particular the acceptance of this basic view of sleep should be of fundamental help to sufferers from agrypnophobia, and the "threat" nature of arousal underlines the importance of anxiety in the maintenance of unwanted wake

The importance of insomnia and dyssomnia in the production of unhappiness and ill health cannot be exaggerated It is along the lines described above that we shall reach a solution of the problem

I am indebted to the late Prof Samson Wright for helpful criticism

Parliament

Taxation and Public Expenditure

THE burden of taxation which this country carries and its pressure on the professional classes was one of the main themes of the debate in the House of Lords on March 6 It was recognised that if taxation was to be eased it could only be done by a reduction in public expenditure, and this led several noble Lords to a reconsideration of our social services

Indeed if we were to achieve any big saving in domestic expenditure we must, Lord BALFOUR OF INCHRYE maintained, do "some basic re-thinking" He readily agreed that the Welfare State must continue to safeguard citizens against such unavoidable hazards as sickness and old age But he believed that we must throw over the idea which had crept upon us that a Government could do better for the citizen and could spend better for the citizen than a citizen could do for himself if he were released from the present rapacious tax system The practical application of a revolt against the Government as the spending agent for the citizen would be no subsidised rents for four-figure incomes, no food subsidies, and no free health-service benefits for those who could afford to pay for their own doctors Against this could be set a level of personal taxation which would allow a man to order his affairs as he wished, to order his own housing, to feed his own family, to doctor as he wished and to educate his children as he wished

The EARL OF CROMER suggested that the Welfare State was designed against the background of the past but had to be paid for at the cost of the present Too much of the cost of the Welfare State was devoted to relieving wage-earners of what unhappily they could not afford twenty five years ago, but today in general happily could afford. It was absurd and unrealistic to expend too much of our energies trying to mitigate the hardships of the past We needed them all to overcome the problems of the present, of which undoubtedly the paramount one was our economic survival, and he reminded noble Lords that of the total Government expenditure of £6000 million a third was on the Welfare State If a man was working his wages should be at a level to provide him with a decent standard of living Such funds as the nation could make available for welfare should be devoted primarily to the care of those who could not care for themselves, and to protect those whom society could not look after in the normal sense Lord Cromer could see no justification in this day and age for large-scale largesse to the population as a whole—such as, for example, family allowances He suggested that the Welfare-State costs might be divided into two categories the first covering those items which the normal Christian morality demanded of the State—such as National Assistance and the like—which should be left as a charge against the Budget as at present The second category, covering other items of the Welfare State, might come under an entirely separate social-security budget which would not have recourse to the general Exchequer, but be financed by National Insurance contributions and by part of the proceeds of purchase tax or a special sales tax. This scheme would have the merit of disillusioning those who believed that they were getting something free, and would produce an awareness of the truth of the situation, which was that the Welfare State had to be paid for, not by someone else, but by every working member of the community

A less drastic reform, put forward by Lord MOYNIHAN, was for some relief from taxation for people who saved to send their children to schools outside the State system of education, or who chose to go to their own private doctor Why should not a citizen spend a little of the money he might have in having just a little more than the State would give him ? But in doing that, why should he be forced to pay for his medicines, whereas other people who did not take the trouble got it all free ? These two were surely blatant attempts at bringing the standard of the people down to a level, rather than trying to raise it

In replying for the Government VISCOUNT HAILSHAM showed a demure pre-budget reticence which happily left him free to turn to the broader issues raised in the debate We were admittedly living in difficult times—he later described them as "abounding prosperity and extreme economic precariousness"—but he thought it wrong to paint the picture in too gloomy tones When he went about the streets and saw the children vigorous, straight-limbed, well clad, with bright faces and obviously never under-nourished, he could not regret the changes of recent years

We were spending, he continued, about £1600 million on social services, and as far as education was concerned he did not think we were spending extravagantly—£514 million or less than 3% of our national product But he admitted that many of the evils against which we planned our social services had not come about The Beveridge report and the white-papers which succeeded it were all based on the belief that we were going to have about 10% unemployment He believed that the social services could have been designed more economically if it had been fully apprehended that we were going to have for fifteen years at least (and he hoped it would last much longer) full employment

The health service plan was based on an expenditure of £175 million a year Sir Stafford Cripps thought that he would limit it to £400 million a year At the latest figures it was running at something like £690 million a year These were startling figures As Lord Hailsham saw it, the National Health Service, if not properly controlled, would run away with a great deal of our national resources Pension funds would be in the red somewhere about the middle of next year, to the tune of £40 million By about 1970 the cumulative deficit would be about £380 million Unless fairly stern measures were taken the budgetary situation for our social services would face a serious financial crisis much sooner than we expected What then were we to do? Abandon the social services for which many people had spent part of their lives? He thought that would not be the right course but he thought that some greater charge for them must be made if they were to be maintained, and if honest finance was to be retained

In a system of full employment a country was entitled to look to wages and salaries as primary sources out of which the ordinary necessities of life ought to be met It was true that needed to be qualified by the insurance principle We had learned to pay while we were well for what we might suffer when we were sick At the same time, we had all to be on guard against the belief that we, as a nation or as individuals, had a right to a gradually expanding standard of life always at the expense of other people As he saw it, inflation was nothing more or less than a large number of individuals making on the cumulative resources of the country a large number of demands, amounting, in fact, to a bigger total than the cumulative resources were able to meet We must remember that in times like this it was not only Governments but countries and systems of government which were on trial If we would not face the necessity for spending enough on investment and education, but continued to spend more on enjoyment than we spent on the true necessities of life, we should find that the dictatorships would beat us in the race for the control of the world

QUESTION TIME

Hydrogen Bomb Tests

Mr Frank Allaun asked the Prime Minister if, in view of the cumulative danger of nuclear explosions to this and future generations, he would consider postponing the hydrogen bomb explosion over Christmas Island for six months, during which period Her Majesty's Government would take the initiative in seeking international agreement to stop all future tests —The Prime Minister replied I understand that the Medical Research Council have no evidence that the amount of strontium 90 and other radioactive particles released by hydrogen bomb explosions which may become sources of internal radiation has reached a potentially dangerous level The present and foreseeable hazards, including genetic effects, from external radiation due to fall out from the test explosions of nuclear weapons, fired at the present rate and in the present proportion of the different kinds, are considered to be negligible Accordingly I am not prepared to postpone the forthcoming test in the Pacific

So far, however, as long term policy is concerned, the policy of Her Majesty's Government has been clearly defined I would add that various proposals on nuclear and conventional disarmament will be considered when the Disarmament Subcommittee, of which Her Majesty's Government is a member, meets on March 18

Mr W N Warbey When did the Medical Research Council give the Prime Minister this information?—Did the council take into account the new evidence produced by Dr Libby, the American Atomic Energy Commissioner, which according to a report in *The Times*, shows that the level of strontium 90 in the bones of Americans will reach, by 1970, a level which will already be as dangerous as that laid down in the standards of the Medical Research Council? In view of the great importance of this matter to human beings now living, including children, and to the future of the human race will the Prime Minister look into this matter again?—The Prime Minister Yes, Sir The Medical Research Council's report was, of course, published last June The Council is in continuous touch with this matter All I can say is that the information which I have given is that which is supplied to me I would point out that the banning of tests is quite a different question from that of their possible limitation All these matters Her Majesty's Government are always ready to consider What I am not prepared to do is to postpone the the tests which we are about to make and which put us as a nation in the position in which we have a right and a duty to be Mr Allaun Since the new American evidence shows that we are in real danger of visiting the sins of the fathers on the children, not only to the third and fourth generations but far beyond that, will the right hon Gentleman have another look at the proposal of postponement?—The Prime Minister Of course, we keep all these matters under consideration, but when I am told that the dangers are negligible, as at present, it is not a reason why we, of all countries, should deprive ourselves of a weapon necessary for our safety

Mr Hugh Gaitskell The Prime Minister will recall that Sir Anthony Eden gave us an undertaking that the Government were prepared to try to bring about a separate agreement on H-bomb tests May I ask the Prime Minister, therefore, whether it is the intention of Her Majesty's Government, when the Disarmament Subcommittee meets on March 18, to put forward definite proposals for abolishing these tests, independently of any other disarmament agreement?—The Prime Minister That is a question we would certainly consider The banning of the tests is one thing and their limitation is another What I am not prepared to do, and I do not think the country or the House would wish, is that we alone should deprive ourselves of the tests at this particular moment thus leaving ourselves in a position of inferiority to others Mr Gaitskell Will Her Majesty's Government put forward separate proposals, at any rate for limiting, with a view to their eventual abolition, such tests, independently of any general disarmament agreement?—The Prime Minister We would rather have a comprehensive agreement dealing with the reduction of armaments both in the unconventional and the conventional fields That is what we would like and what we have been working for Short of that, if we cannot get that, we should be anxious to get any limitation of tests agreement

Dr Edith Summerskill Is the right hon Gentleman aware that the statement which he has just made is considered out of date by authorities, and that it cannot be reconciled with the statement which was made within the precincts of this House last week by Professor Haddow, who is regarded as the greatest authority in this country on this subject?—The Prime Minister Governments can only rely upon the best authorities that they can find The best authorities available to Her Majesty's Government are the authorities which we normally consult and whose opinion I have quoted These are not individual experts here and there, but the Medical Research Council which, I think the right hon Lady will admit, comprises the best organised and the most efficient research on this matter that can be found

North Staffordshire Infirmary

Mr Ellis Smith asked the Minister of Health when it was intended to implement the promises made to the hon Member for Stoke on Trent, South, that the urgently required extensions would be made to the North Staffordshire Infirmary —Mr Dennis Vosper replied The regional hospital board has included in its capital programme a new casualty and accident department, which it is hoped to start building next year Mr Ellis Smith While attributing no responsibility in the matter to the present Minister, will the right hon Gentleman see that this matter is now given super priority ? Is he aware that the hut which is now housing a great surgeon and a very fine staff of nurses, together with disabled miners and others, was built in the first world war and was used for a soldiers' sports centre ? Is it not disgraceful that we should have expected these very fine people to have carried on for so long in these appalling conditions, and will he not give the matter super priority ?—Mr Vosper I am aware of what the hon Gentleman says, and that is why this project is in the 1958–59 programme In fact, I understand that some preliminary work is in the 1957–58 programme

Mr Ellis Smith What representations has the Minister received during the past years about the urgent need for extensions at the North Staffordshire Infirmary, Stoke on Trent , what kind of facilities exist there in the huts built of wood , is the accommodation satisfactory ?—Mr Vosper Representations have been received during the past three years from the hon Member for Stoke on Trent, Central (Dr Stross), and the hon Member for Newcastle under-Lyme (Mr Swingler), as well as from the hon Member himself A large wooden hut is in use for the accident follow-up clinic, and a similar one for the skin department The accident accommodation is not satisfactory, and it will be replaced by the proposed new casualty department Comprehensive treatment facilities are provided for the injured in the main hospital building

Prison Doctors

Dr Barnett Stross asked the Home Secretary how many medical practitioners are employed full time in prisons in England and Wales , and of these how many hold the diploma of psychological medicine —Mr J E S Simon replied 49 and 6, respectively Dr Stross Would it not be reasonable to ask that when any improvements are made in the service a special point should be made of ensuring that as many medical men as possible who serve full time in the prisons should have the diploma and that outsiders coming in to assist should also, where possible, be skilled in psychological medicine ?—Mr Simon In the case of applications relating to the prison service, the diploma is regarded as an advantage but not a prerequisite or essential, because the posts do not involve full time psychiatric work When an outside consultant is brought in, he is always a specialist

The Royal Commission on Remuneration

The Prime Minister announced on March 12 that Sir Harry Pilkington, a company director, a director of the Bank of England, and a former president of the Federation of British Industries, has been appointed chairman of the Royal Commission The other members are

Mrs Baxter (aged 54), secretary, Cambridge University Women s Appointments Board

Mr A D Bonham Carter (51), a director of Unilevers

Mr J H Gunlake (53), vice chairman Institute of Actuaries

Prof John Jewkes (54), professor of economic organisation, Oxford

Mr I D McIntosh (49) Headmaster, George Watson's College Edinburgh a member of the Committee on Recruitment of Dentists

Sir David Hughes Parry (64), professor of English law, London University

Sir Hugh Watson (54) deputy keeper of Her Majesty's Signet

Mr Samuel Watson (59) Secretary Durham Miners' Association , chairman of an N H S executive council

The Prime Minister said that the pay of junior hospital medical and dental staff, up to and including the grade of senior registrar, will be increased by 10% from April 1 " We are also considering," he added, " what should be done by way of interim adjustment for other doctors and dentists covered by the commission's terms of reference I shall make a further statement on this matter in due course "

University Salaries

Parliament is to be asked to vote additional funds allowing universities, as from August 1 next, to pay higher salaries to full time staff The necessary increase in the recurrent grant is estimated at £3 million initially For non-medical and preclinical professors the salaries will be £2300 to £3000 a year, according to post For clinical professors they remain at £2500 to £3100, with increases for juniors

In England Now

A Running Commentary by Peripatetic Correspondents

Hurrah for the deep, deep peace of a flat in town in place of the hurly-burly of the weekend cottage, as Mrs Patrick Campbell might have said Not having lived in the real country since I was a boy, I had forgotten what a ceaseless war has to be waged against its denizens in fact, except for mining it's the nearest thing to war in peacetime that there is Up in the night to stop the rats moving the furniture around until you won't recognise the room in the morning Then the dawn patrol against the rabbits, who, like the enemy on most dawn patrols, aren't there " Born and bred in a briar patch " they may be but the local Ole Doc Bunny evidently prescribes the choicest treasures of the rock garden as a diet for convalescent myxomatosists Round the house to take the mice out of their traps and dispose of them After breakfast, out against the pigeons, who can distinguish a gun from a stick at 50 yards with the sun in their eyes But I can still put a shot in a grey squirrel's drey and get a fircone on the head—and no squirrel Then the moles, who have made the lawn look like a lunar landscape The moles ! Some say worms baited with arsenic or strychnine but we do not hold these views Others say cyanide, but we have tried this and it doesn't work Some advocate running the exhaust from the car into the runs for twenty minutes but who, except spivs, has got twenty minutes' petrol to spare ? And the chap from whom we borrow the mole-traps never seems to be at home When all else fails there are the slugs which (are slugs which or who ?) have eaten the primula seedlings, the moths in the carpet, the worm in the chairs, and—by Monday—the bats in the belfry

* * *

Into the E N T *outpatients department* of this large Canadian hospital walked a rather elderly gentleman with his hands clapped to his mouth

" Zzzzz," he said, urgently, to the sister in charge

" Comment, Monsieur ? "

" Aaah ! "

" What is it that you want ? "

" Rrrrrr "

This history, though somewhat lacking in detail, secured entry to the surgeon On examination, a piece of something about the size of a grape was discovered grasped somewhat insecurely between the fingers, and most securely between the teeth Nor would the patient release his grip until it was safely held by forceps Endoscopy then revealed the object to be a nasal polyp which had attempted to enter the glottis It was promptly rejected with such explosive force that it was hurled through the mouth, and out of the lips, until arrested by reaching the end of its somewhat elongated pedicle At this stage, the patient, finding the pedicle between his teeth, had fixed it firmly, and sought help

* * *

How long is a piece of string ? My wife is worried about our pigs We seem to be rearing some curiously elastic variety In case you do not know all the undertaking secrets of the mortuary, the patient is measured up by two official ghouls, one being a gentleman from the National Pig Progeny Testing Board, and the other a grader from the Ministry of Fish and Chips, none the less gentlemanly in the silent presence of those little darlings who pay our rent We could never fathom how there was always about 1 in between them Now we know The grader measures the length of the pig while the carcase is hanging, his colleague while flat on the slab One regards our dear departed as just another hunk of meat The other shows true professional delicacy Bacon factories contain a curious mixture of hopes and fears

Such anomalies strike at the very foundations of anthropometry For many years my wife has made our pyjama-clad little figures stand bolt upright against the bedroom door, with *Price's Medicine* on their heads, while I searched for a scalpel to scratch on the paint Ought we to have looped a dressing-gown cord over the clothes hook and measured them downwards? Would some less weighty tome than *Price* have affected their compression? I doubt if we shall ever know We have long suspected that boarding-schools practise some such expansion-and-contraction technique to puff up their catering claims Even their own figures suggest that our children must shrink in the holidays Maybe we too should keep a rack in the cellar

But the diversionary art of London's escalators asserts that whatever may have slipped in the way of anthropometry can be adequately compensated by the one-way linear stretch, the two-way area stretch, or the three-way cubic s-t-r-e-t-c-h in our new foundation garments Measurements are becoming so relative that before long we must expect another set of little brackets to augment those elementary metric conversions sprinkled all over our journal I can see no limits to tension, short of disruption, and might not some of the world's present troubles be due to one set of people measuring an object hanging and the others measuring it flat, when they are both really measuring the same thing?

* * *

Time off in February or March is often useless Where can one go in this climate? Staying at home to paint the house is tolerable only in small doses and is apt to be interrupted by calls from hospital This year I discovered the Isles of Scilly I went by boat from Penzance (about 3 hours) but those anxious to escape more quickly from civilisation and avoid a possibly stiff dose of the Atlantic can get there in 15 minutes in a tiny aeroplane from Land's End

On arrival there is certainly a feeling of being abroad and a sense of surprise to find English spoken The oldest inhabitant told me of the days when wrecks were common, and on Tresco I saw an interesting Valhalla full of figureheads and odd objects collected from wrecks Many TV aerials are to be seen, but the chance of meeting a car on a nine-mile tramp round St Mary's is slight and the drone of an aeroplane engine is only heard for a brief period On the off islands of St Martin's, St Agnes, Bryher, and Tresco one can really escape completely from the sounds of modern civilisation

The flowers, mostly daffodils, grow in small fields protected from the south-west wind by evergreen hedges But anyone expecting to see bright fields of colour will be disappointed, for the flowers are picked as soon as buds appear Only those spared by an uneconomic price are left to blossom in the field I don't think there is much soil in the Scillies and many of the 140 islands which are uninhabited have none Even grass does not grow on them and by this criterion (Leland's test) they are mere rocks or sandspits the others make up for their Cornish ruggedness by their Mediterranean climate

Theatre Sister to *Staff Nurse* "Mr Phillips will not be turning up till 9 30 tomorrow, but Simpson is starting at 9"

Not very illuminating, perhaps, unless you happen to know that Phillips is the theatre porter and Simpson the consultant surgeon

* * *

We, in Scotland now, who try to maintain high educational standards, have always looked with a little suspicion at the apparent ease with which Sassenachs can obtain the degrees of M B, CH B at English universities Imagine our surprise then, when on looking through the *Occupational Tables, England and Wales, 1951 Census* (H M S O 1956, and costing *£7 7s mark you*!) we discover there were in England and Wales four medical practitioners whose age last birthday was 15, three aged 16, one aged 17, and four between the ages of 18 and 19 years Can it be that, having failed the 11+ examination, instead of going up to the much vaunted public school, English children are now being sent up to medical schools?

News from School—As Lent has begun we ought to give something up which we have always said, before, was essential for us. I wonder what would happen if I gave up my food? So far I have'nt given anything up especially sweets, because people are more ready to give them away now, as lots of people have given them up

Letters to the Editor

GOVERNMENT AND PROFESSION

SIR,—Age having caused my retirement just one year before the National Health Service came into action, it is quite impossible for me to assess, in pounds, shillings, and pence, what are the right amounts for the various services and ranks to receive as annual emoluments, yet would I implore all my brethren in our profession to refrain from taking any further part in that strike which is-not-a strike On three former occasions this has failed because the partakers in it realised at the last moment that they could not possibly be parties to so disloyal an action

Today we are in as grave a position as the country ever has been since the end of the Napoleonic wars, and are entering in that second decade after the death of Hitler which corresponds with that which after the fall of Bonoparte preceded the Reform Bill We have been through two wars that have drained us of our wealth, and since then have had Korea to pay for and now there is Suez In this next decade we shall need all the spirit of fraternity that human nature is composed of to get through without grave disturbances

Everyone is feeling the strain, from those who live in great houses and wonder how they can keep them up, to those in the little ones whose daily dread is that they may again be driven down to the standard of living of the first years of this century when the food of many of our children was "bread and marg" for breakfast, dinner, and tea This is not the time for us to take any action, other than by the accepted methods of discussion

Much as many of us may think its methods need amending, trade-unionism has become the accepted means for those who work primarily with their hands This does not mean that anything resembling it should be the means for those that work primarily with their minds—as it has been made since 1911 by those who have claimed to be our leaders Even setting up the organisation is harmful, as it clogs the machinery of proper discussion

It has done so in the past, it will do so again As a private individual, therefore, I beg everyone in the profession to refrain from signing any documents that they may very soon have cause to regret, and will feel bound to repudiate

London, W 1 T B LAYTON

TOWARDS PREVENTING SUICIDE

SIR,—One of the medical members of the Samaritans has drawn my *attention to* Mr A Watney's letter last week The service he envisages has been in operation since November, 1953, when, on my appointment as rector of a City church with minimal parochial responsibilities, I secured the kind cooperation of the national press in inviting anyone who was in *despair* to use MAN 9000 as a sort of spiritual "999"

The calls began coming in at once, and over *650 troubled* people, of whom some 300 appeared to be potential suicides have been persuaded to come and discuss their problems, the commonest of which are lack of a faith to live by, psychological disturbance, marital or other sexual *maladjustment*, and loneliness in the world's most populous city In addition to our "clients," over 150 people have offered to help, and more than half of these are still as active as their circumstances allow Some of the most effective first came as *clients* Our only full time staff apart from myself are a secretary and a telephonist (our telephones ring over 100 times a day)

Our experience has proved the truth of Mr Watney's contention that many suicides can be prevented by "a sympathetic listener and counsellor" Few of our members are armed with anything more than compassion and common sense plus the training we are able to give at our meetings, yet their intervention in the spirit of the Good Samaritan may make all the difference. Only two of our clients have so far committed suicide, though another half-dozen are still in danger of this.

I cannot agree that "helpers should not belong to medical or religious bodies, nor should they be trained social workers or psychiatrists" if Mr Watney means that these should be excluded. The collaboration of medical and lay psychotherapists is essential in many cases, and where there is serious mental disturbance we feel a heavy burden of responsibility until we have won the sufferer's confidence sufficiently to persuade him or her to allow us to obtain a *qualified* opinion. The collaboration of one or two trained social workers has pointed the way to avenues of practical help we might otherwise have been unaware of, and if we were to exclude members of religious bodies we should be reduced to about ten volunteers who give invaluable help but obviously cannot be expected to deal with the many theological difficulties and problems of conscience which come our way. But if Mr Watney means that astonishing successes can be achieved in this work by "ordinary people," especially if they have "been through it themselves" I can assure him that this has been proved up to the hilt.

The broadcast about our work by Stephen Grenfell in the Light Programme last month, and its discussion by the Critics on the Home Service, have not only inundated us with calls from the London telephone area which we regard as our "beat," but have also greatly added to the number of letters from other parts of the country and from abroad. It is clear that a similar service ought to be in operation in all the great centres of population. I am in touch with the work that has started in the last year or so in Berlin (where a psychiatrist who is also a Lutheran pastor is in charge) and in Sweden, but if anything of the kind is going on elsewhere in this country I am unaware of it. I have had inquiries from people in the Provinces willing to help if we will extend, but whilst close links and exchange of experience would be indicated if there were "Samaritans" in all the big towns, it would be undesirable and indeed impossible to organise them from London. We should naturally be willing both to invite leaders to work with us for some weeks, and also to visit other towns to help a newly formed branch to avoid our past mistakes. An active part would need to be taken by a clergyman who did not regard clients as conversion-fodder, a psychiatrist who took people's spiritual needs seriously, a lay psychotherapist working under medical supervision, someone in addition to the clergyman with experience of marriage guidance, a social worker, and a lawyer, and these "experts" would need to be surrounded by a devoted band of people of all religious faiths and none to do that most vital work without which all the rest may be in vain, and which we call "befriending."

I should like to warn anyone who is thinking of starting this work that once it has begun there will be no time to raise the money necessary to keep it going. We innocently imagined that sooner or later (and we hoped not *too* late) someone would notice that we were working understaffed in appalling conditions, and would consider that 3½ years on a shoestring had proved that the idea was sufficiently promising to be worth financing properly. This has not happened, and I would advise prospective anti suicide squads to make sure of adequate premises and funds before committing themselves to anything up to 100 hours a week of the most exacting (if also the most rewarding) work imaginable.

St Stephen's Church
Walbrook, London, E.C.4

CHAD VARAH

NEW DRUGS, OLD DANGERS

SIR,—Your editorial warning (Feb. 9) rightly draws attention to the dangers of toxic reactions to drugs but, as Dr Fraser and Dr Doniach say (Feb. 23), it is unfortunate that a drug of such proven efficacy and safety as carbimazole should be stigmatised by association with the amidopyrine derivatives or even phenylbutazone.

In neither of the above communications was a further interesting point mentioned. In the treatment of other than the mildest degree of thyrotoxicosis, three alternatives are open—radio iodine, surgery, and anti-thyroid drugs. It is not yet certain whether therapeutic radio iodine may eventually have a carcinogenic effect. Surgery has a mortality-rate of at least 0.24%[1] and an appreciable morbidity. Anti-thyroid drugs occasionally cause toxic reactions, but carbimazole appears to be the safest at present available;[2] though many thousands of patients must have been treated with carbimazole, the third fatal case has only just been reported.[3]

Without discussing their relative merits, I would point out that treatment by thyroidectomy has a higher mortality than treatment with anti-thyroid drugs.

Cardiff Royal Infirmary

CRAIG BURRELL

BRONCHIAL CARCINOMA

SIR,—Many of us will find the plea put forward by Mr Thompson (Feb. 23) unacceptable as a rational step towards improving the treatment of this condition. It is true that, as Mr Thompson says, "the difficulties in diagnosis are the real problem" but it is unfortunate that the stress in his comments should focus attention on an aspect of delay that does little justice to his colleagues' efforts, particularly as it has yet to be shown that the earliest possible diagnosis of this condition is, in fact, early enough to justify considering surgery as the treatment of choice.

Without planning especially for any lung condition the hospital service in this area has, for over seven years, provided general practitioners with both X-ray and pathological services, which are freely available, as is access to the thoracic surgeon. The conditions which Mr Thompson advocates have, in fact, existed for a good while, and it is interesting that the almost invariable step of the general practitioner, after getting his X-ray, is to turn either to the consultant physician or to the chest clinic for further investigation. Reports on chest X-rays from hospital departments, though frequently worded in such a way as to indicate probable pathological conditions, are nevertheless commonly couched in terms which cannot indicate to the general practitioner a clear need to turn to the thoracic surgeon. It is presumably at this juncture that Mr Thompson desires a "cancer differentiation clinic" and, although, with suitable rearrangement of the radiologists' phraseology and the general practitioners' habits, new referrals might be less than some of your correspondents forecast, they would necessarily have to be numerous to make any impact on mortality, as I think the following figures indicate.

In this area, of a population of roughly 140,000, during 1956 24 cases of bronchial carcinoma were diagnosed at the chest clinics. Of these, 8 arose in patients already under supervision on account of tuberculosis and/or pneumoconiosis, while 16 were new cases. In 15 others bronchial carcinoma was provisionally diagnosed, and 9 of these were bronchoscoped. 1 patient deemed tuberculous was found to have a neoplasm after ten weeks—the diagnosis was missed in fact. Of the proven group of 24, 11 died during the year. 4 patients had obvious metastases when first seen, 4 others were found to have metastases within two weeks of first attendance, 5 others had bilateral pulmonary tuberculosis (sputum positive in 2), a further 3 had complicated pneumoconiosis category B (Pneumoconiosis Research Unit classification), 2 more refused admission to hospital for either bronchoscopy or deep X-ray therapy, 4 were deemed inoperable by the surgeon by virtue of respiratory insufficiency or advanced age, and 2 were submitted to pneumonectomy and survive. The operability-rate was thus about 8%, and the patients found suitable for operation came from *symptom free* attenders for mass miniature radiography.

Now for the delay: of 17 bronchoscoped the average time between first interview at the clinic and admission for bronchoscopy (always after consultation with the surgeon) was 16 days—a figure materially influenced by 4 patients who, despite every encouragement, held back for 49, 30, 26, and 24 days before agreeing to bronchoscopy. 4 patients (none of them submitted to bronchoscopy) had, in fact, attended hospital for X ray previously, the report going to the general practitioner, and as this is the procedure Mr Thompson favours, their fate is worth following The time which elapsed between the hospital X ray report and referral to the chest clinic was 332 days 71 days, 40 days, and 39 days In the *1st case the patient failed to reattend hospital for further* X rays as requested and there was inadequate follow up by the X-ray department, in the 2nd, delay appears to have been the general practitioner s procrastination, and in the 3rd and 4th cases a firmly made but incorrect radiological diagnosis from the hospital gave the practitioner no hint of the possibility of neoplasm, and a routine appointment at the chest clinic was thus asked for

YOGURT IN GASTRO-ENTERITIS OF INFANCY

SIR,—I have read with interest the correspondence on this subject Yogurt seems to be established as a remedy In eastern parts of India (Bengal and Assam) yogurt is used by village women who regard it as a specific treatment for gastro enteritis in infants and adolescents

Edinburgh
A K CHATTERJEE

A NEWSPAPER FOR THE PARTLY SIGHTED

SIR,—Dr Atkinson's letter of Feb 2 raises the problem of helping the partially sighted to read He suggests the solution may lie in the provision of reading matter printed in type large enough for them to decipher This possibility has already been examined carefully by the educationalists in regard to school books for the partially sighted and found impracticable at present on the grounds of cost of production and limited demand

There are now many devices in the form of hand lens, lens mounted on stands, telescopic lenses, and high power spectacle lenses giving various degrees of magnification up to 15 A special clinic exists at Moorfields Holborn Branch, in London, for providing these aids The aims of the clinic are to find out the needs of the patient and supply the most appropriate aid Some training and encouragement in the use of the appliances in the higher ranges of magnification is found to be necessary Visual aids successfully prescribed give the patients much wider scope than could ever be obtained by the limited production of reading matter in the larger type which would be required

I hope Dr Atkinson will not take it amiss if I suggest that he refers his partially sighted patients to his ophthalmic colleagues, who are fully aware of these appliances and can obtain them for their patients from their local dispensing opticians

London, W 1
P McG MOFFATT

SIR,—Dr Atkinson has drawn attention to the misfortune of those many and often elderly people whose visual acuity is so impaired that they can read type only of newspaper headline size He suggested a special newspaper composed wholly of headline typefaces —a suggestion which poses many problems of which expense is not least

The difficulties of the partially sighted have been prominent in the activities of members of the Association of Dispensing Opticians for many years Telescopic spectacles were produced a half century ago, special magnifiers have been manufactured since the 1920s and made known to ophthalmic surgeons Since 1950, telescopic spectacles of increased power and improved magnifiers of greater field of view have been made available, more recently dispensing opticians have devised reading spectacles permitting magnifications of 4×, 6×, and 8× to be used, and these can be obtained through ordinary trade channels

A system of quantitative assessment of the degree of magnification necessary has been advanced by one of my members and this is the subject of systematic tests for patients at the Westminster branch of the Moorfields, Westminster and Central Ophthalmic Hospitals in London The same member has produced ingenious combinations of illumination and magnification extending the range from 8× to 20×

The Oxford Ophthalmological Congress in July, 1956, made the question of aids to the partially sighted one of its principal subjects for discussion, and the important part to be played by the dispensing optician was recognised when the president and the vice-president of this association were invited to contribute to the opening papers

The problem voiced by your correspondent is therefore being met by ophthalmologists and dispensing opticians, and its solution will render newspapers of enlarged type unnecessary

The Association of Dispensing Opticians,
London, W 1
M G AIRD
Secretary

ÆTIOLOGY OF PRE-ECLAMPSIA

SIR,—May I answer certain criticisms that time did not allow me to deal with at the meeting at the Royal Society of Medicine on Feb 22, reported in your columns last week ?

Renal ischæmia, Pappenheimer's study has shown,[1] can remain undetected it can provoke a rise in blood pressure, and Wilson[2] draws attention to the possibility of an undetected renal mechanism underlying essential hypertension, it can account for *all* the signs of toxæmia and be provoked by the uterorenal reflex,[3] which is the primary and effective, *but not the sole*, stimulus for its production in toxæmia

Professor Browne's experience of serious deterioration of toxæmia after surgical induction is thus accounted for by the excitement of operation, the anæsthetic, the cervical manipulation, and the heightening uterine tension of incipient labour (a supreme adverse factor), which can all increase the renal ischæmia and often help to outweigh the benefit conferred by reducing the intra uterine *pressure* by amniotomy

Renal ischæmia is more likely in pregnancy complicated by essential hypertension—a clinical state where I *suspect* it already exists undetected by our hitherto incomplete appreciation of renal hæmodynamics measured biochemically Renal ischæmia is reflected in the reduced uterine circulation—a change noted also in the pregnant woman suffering from essential hypertension Its occurrence and extent depend on the responsiveness of the kidney, which occasionally varies greatly from patient to patient, thereby largely explaining the also occasional apparent exceptions to the thesis, when even a small fœtus can evoke the renal ischæmic reflex, though a larger one may fail to do so Similarly, as Dr Morris pointed out, a pregnancy complicated by twins or by acute hydramnios is not always a toxæmic one In these circumstances the adaptation of the uterus to its contents also affects the extent of the renal ischæmic response Such adaptation is the measure of the uterine tension (the stimulus of the reflex), and is not to be confused with the intra uterine pressure, which is a minor factor in the production of the tension

The foregoing helps to explain the difference in the incidence of toxæmia when these identical pressure factors (twins and hydramnios) complicate either the primigravid or the multiparous state

Dr Morris raised another point of peculiar interest by citing that toxæmia is not an invariable accompaniment to pregnancy in a rudimentary horn I would like to offer the following explanation Grunewald[4] found an association between the failure of development in the uterine horn on one side and absence of the kidney on *the same* side There may be a physiological counterpart to *this* embryological connection each uterine horn may exert its reflex ischæmic action on the corresponding kidney alone Thus the kidney on the side of the normally developed and non pregnant *horn* would *not* have been subjected to reflex ischæmic stimulation. It would therefore be free to neutralise the humoral hypertensive substances produced by its ischæmic partner and also to deal with the additional salt and water load. Experimental parallels are provided by Kolff and Page[5] and by White.[6]

---

[1] Pappenheimer, J R, Kinter, W B *Amer J Physiol* 1956 185 377

[2] Wilson C Ledingham, J M *Brit med J* 1956 ii 1236

[3] Sophian, J *Toxæmias of Pregnancy* London 1953

[4] Grunewald W J *Anat Rec* 1939, 75 237 *Ibid* 1943, 86, 321

Finally, Franklin's[7] "hæmex" effects responsible for renal ischæmia may well underlie the association of toxæmia with extra uterine pregnancy, since blood and certain other substances spilled on the peritoneum can provoke a renal shutdown.

The correct appreciation of the thesis I have advanced is therefore sufficient to explain these apparent exceptions. Its main themes are that the primigravid uterus by resisting stretch imposes renal ischæmia, and that this change is responsible for the pre-eclamptic syndrome. Both remain unshaken is my submission.

London, W 1 JOHN SOPHIAN.

ACETAZOLAMIDE IN THE TREATMENT OF CYSTIC DISEASES

SIR,—We have made an observation which we find quite appealing but are unable to pursue because of lack of suitable patients in our military practice. It is with the hope that readers with suitable patients will investigate the effects of acetazolamide ('Diamox') on cysts of various organs that these superficial observations are presented.

For about a year we have been caring for a 37-year old white woman whose only complaints have been referable to chronic cystic mastitis. Shortly after hysterectomy for "abscessed uterus" in 1949, she first noticed swelling, tenderness, and spherical nodules in both breasts. Over the years the breasts became larger and more tender, and their very weight caused pain in spite of reinforced supporting devices. Progesterone therapy seemed to provide some temporary relief, but at the time of her first visit to the clinic she was quite miserable most of the time. The breasts were enormous, turgid, hyperæmic, and too tender to palpate adequately. There was no other evidence of disease; and urinalysis, blood counts, and chest X-ray were normal. She was examined by a surgical consultant, who was willing to defer surgical intervention.

Progesterone therapy was reinstituted, but no definite improvement ensued and after four months it was apparent that some other measure was mandatory. Because of a possible analogy between secretory cysts and glaucoma, acetazolamide (2 acetylamino-1, 3, 4-thiadiazole-5 sulphonamide) 250 mg was prescribed for each eight hours for three days twice a month. A few days later the patient telephoned joyfully that the pain and tenderness had subsided completely, that her breasts felt light and buoyant, and that the size had so diminished that she could wear comfortably a brassiere several sizes smaller than had been possible for years.

When she returned the following month she described a gradual refilling and increasing tenderness of the breasts after the first detumescence and an equally striking response after the second course of acetazolamide. At this time the breasts were pale, flaccid, wrinkled, and pendulous, and palpation revealed grape like clusters of firm nodules about 1 cm. in diameter, which were non tender. Her weight was 2 lb less than the previous month, and she believed that her feet and ankles were slimmer, although the first examination had revealed no œdema. The regimen was changed to three days of acetazolamide therapy each week, and in the past nine months the patient has had no recurrence of her symptoms.

It was unknown whether the improvement from acetazolamide was a result of reduction of generalised œdema which was apparent only in the breasts and for which there was no obvious cause, or whether there was a specific effect on the cysts themselves. If, like the ciliary body of the eye,[8] the cysts secreted bicarbonate to increase their osmolar, and hence their water, content, inhibition of carbonic anhydrase might cause a reduction in cyst volume. To investigate this possibility, cyst fluid and plasma from a second patient, who had a solitary breast cyst of some 50 c cm volume, were examined before and after a three-day course of acetazolamide with the results shown in the accompanying table.

BIOCHEMICAL FINDINGS IN A CASE OF SOLITARY BREAST CYST

—	Plasma		Cyst fluid	
	May 17, 1956	May 21, 1956	May 17, 1956	May 21, 1956
Na (m.eq per litre)	135.6	142.7	148.5	62.4
K (m.eq per litre)	4.8	3.3	10.0	99.9
CO_2 (m.eq per litre)	27.3	20.2	15.5	31.3
Cl (m.eq per litre)	104.6	110.7	93.0	32.4
pH			7.39	7.18
Milli-osmols per litre*	309.7	288.4	286.2	285.4

* By freezing point depression

We would not dare attempt to interpret these surprising results until they are confirmed in additional cases, but neither this same patient nor any other suitable one has been available to us. Serious analytical errors are uncommon in this laboratory, and the comparability of the 90 m eq per litre gain in potassium and the 86 m eq per litre loss of sodium by the cyst fluid suggests that a true change has occurred. The initial discrepancy of 50 m eq per litre between cations and anions in the cyst fluid, rising to 100 m eq per litre, with no change in total osmolar concentration, indicates a large and increasing concentration of an unmeasured anion.

Although we have been anxious to find patients with cysts of the breast, we are even more interested in the possibility of a favourable response in cysts of the kidney, where slight relief of pressure might have profound effects on function and viability of the renal parenchyma and, hence, the patient. In the one patient whose renal cyst fluid, obtained by percutaneous needle aspiration, was examined before and after acetazolamide therapy, there were no changes from plasma except those expected from the lower protein content. In retrospect, it might have been predicted that a renal cyst, which is derived from the proximal portion of the nephron and presumably lacks secretory capability, would resemble an ultrafiltrate of plasma. However, this too should be confirmed, and the rarity of such clinical material in a military practice makes it unlikely that we will be able to pursue this project.

POLYNEURITIS AS A CAUSE OF "AMYOTONIA CONGENITA"

SIR,—It is certainly true, as Dr Woolf points out in his letter last week, that amyotonia congenita is a term originally proposed by Oppenheim to identify a condition in which generalised hypotonia of skeletal muscles is present at birth and in which spontaneous improvement occurs. On the other hand, the fact that progressive infantile spinal muscular atrophy (Werdnig-Hoffmann disease) could begin at or before birth was not generally recognised when Oppenheim wrote his original description.[1] Furthermore, it soon became apparent that many cases in which Oppenheim and others diagnosed amyotonia congenita showed steady deterioration and eventually proved to be instances of the progressive disease.[2] Whether or not this was Oppenheim's original intention, it soon became the custom to describe all cases showing severe hypotonia at or soon after birth as amyotonia congenita and few have reserved this name for that small proportion of cases which show spontaneous improvement. Indeed it is now a common practice amongst pædiatricians and neurologists to use the term amyotonia congenita for all cases with muscular weakness and hypotonia developing in the first year of life, even when the condition is obviously one of progressive spinal muscular atrophy Hence I would agree with Brandt[3] that this title is now generally utilised to describe a syndrome which can be produced by many disease entities

In my view, Dr Chambers and Dr MacDermot (Feb 23) were therefore justified in saying that their cases of infantile polyneuritis had presented with the syndrome of amyotonia congenita While I do not wish to deny the importance and validity of Oppenheim's original observations, I would submit that the term amyotonia congenita has become unsatisfactory and is better discarded It is for this reason that I have suggested[4] a new name—"benign congenital hypotonia"—to identify that group of cases which carry a good prognosis

DEPOT TUBERCULIN

SIR,—Dr Hall's letter (March 2) regarding the disadvantages of depot tuberculin prompts us to record our own experience with this substance

Eleven months ago it was given to a group of 42 elderly people who were negative to 100 T U of Old Tuberculin The difference between the reactions to the P P D (purified protein derivative) and to the control oily vehicle was quite definite in those who reacted, but we find that almost a year later the dusky red indurated area persists in a substantial number of patients It matters little in the elderly, but it is understandable how unpopular it would be in younger people

Another curious feature is that the indurated area becomes more red and angry-looking if the patient has an intercurrent infection We have been unable to explain this

BURNS AND SCALDS

SIR,—We regret having delayed our comment on the letter from Mr Watson and Mr McLaughlin[5] At any rate this delay will have given them the opportunity of saying, "There, I told you so, he does graft immediately"

In the past year, more than eighty patients with burns were admitted to our clinic and only one was grafted, this was a little girl who developed, while in hospital and as had long been forecast by us, a contracture beneath the chin Because of their position and her habit of slobbering food over the raw surface, we were never able to keep the granulations dry

Professor Wells is quite right in his evaluation of the Baghdad granulations, and many others of the experienced visiting surgeons who have examined these cases have commented that they have never seen anything quite like them before But we are especially grateful to Professor Wells because he persuaded his colleague, Mr J H Johnston, to visit us in Baghdad and we had the privilege of his criticism and help over an all-too-short period of weeks Working in the middle of a vast desert, it is easy to develop the belief that all one's geese are swans, and a little deflation has a salutary effect

We are grateful for the dogma on the pathology and repair of burns but should like to refer you to what Shakespeare *might* have said in the matter "There are more things in heaven and earth than are dreamt of in your pathology"

For the information of your correspondents, it is theoretically possible to leave London Airport in the early morning and arrive in Baghdad early the same evening

KHALID NAJI

COLDS IN RELATION TO THYROID ACTIVITY

SIR,—The connection between the thyroid gland and the nose has been recognised for several decades[1] Proetz[2] and Hollender[3] reported an increased tendency to upper respiratory disease in their hypothyroid patients, which could be diminished by giving thyroid hormone

I have compared thyroid function, in patients having diagnostic radioactive iodine (^{131}I) tests for suspected thyroid diseases, with the incidence of upper respiratory infections

Patients referred for these tests were asked the following questions

(1) Do you get colds ?
(2) Have you had a cold or influenza in the past two years ?
(3) Do you suffer from sinusitis or catarrh ?
(4) Do you suffer from hay fever ?
(5) Do you suffer from asthma or bronchitis ?

A patient who replied "yes" to any of these questions was classified as positive, and one who said "no" to every question was classified as negative

A tracer dose of ^{131}I, either 50 μc or 100 μc, was then given by mouth on a fasting stomach After twenty-four hours the thyroid uptake of ^{131}I was estimated, and after forty-eight hours the serum protein bound ^{131}I The second test was omitted in 16 hyperthyroid patients who had an elevated basal metabolic rate or well-developed clinical signs Diagnosis was made by methods other than ^{131}I tests in 4 hyperthyroid patients Patients with a high uptake but low protein bound ^{131}I did not suffer from hyperthyroidism[4] The results in 4 euthyroid patients who had had a previous partial thyroidectomy and in a pregnant patient have been excluded, for falsely high values are found in these cases

All the patients in the hyperthyroid group were clinically hyperthyroid, the majority were suffering from toxic nodular goitres The age distribution is shown in table I

The hyperthyroid patients were remarkably free from upper respiratory infection Only about 13% of them had a positive history, compared with 85% of those without hyperthyroidism (see table II, $\chi^2 = 49\ 5$)

TABLE I—AGE-DISTRIBUTION OF PATIENTS

—	Age (years)					
	0–30	30–40	40–50	50–60	60–70	> 70
Hyperthyroid	2	3	3	6	13	3
Not hyperthyroid	9	14	14	17	16	4
High uptake but low protein bound ^{131}I	2	2	0	2	3	2

Hyperthyroidism may affect the nasal mucosa in two ways

(1) Vitamin A has been shown to be present in greater amounts than normal in hyperthyroid persons[5] owing to the direct action of thyroid hormone on its absorption and conversion from carotene Vitamin A is concerned in the maintenance of mucous surfaces[6] and has been

called the *General Practitioner* ran a campaign to persuade those in practice not to allow themselves to be described as doctor unless they held a university doctorate My father, who subscribed to this journal and held the Conjoint diploma, regarded this advice as an unnecessary interference with the wishes of his patients, who had always considered him their family doctor and often their adviser on matters outside medicine

London, W 1 **PEARSE WILLIAMS**

PEDICULOSIS CAPITIS

SIR,—The investigation described by Dr Nelson and Mr Cromie (Feb 23) is full of interest and the observations will be of value to medical officers of health, all of whom must still be concerned with the prevalence and difficulty of eradication of *Pediculus capitis* The authors very rightly call attention to the part played by reinfestation within the family circle and the desirability of treating other members of the household The issue of dicophane preparations to adult members of families in which recurrent cases of *P capitis* infestations occurred among the children has, in my experience, proved worth while

Is there not, however, a tendency to forget that the outstanding property of the new contact insecticides is their *persistence*? If the application is not allowed to remain on the hair long enough (about a week) its value in killing successive batches of lice as they are hatched is lost The instructions supplied by the makers of certain insecticidal preparations, which advise that the hair should not be washed for at least 24 hours after treatment, seem therefore open to question

In a series of cases in which the hair was untouched for a week after treatment no living lice were found, and all the "nits" were empty Possibly if this practice became more general fewer cases of "reinfestation" would occur

Camberwell, London, S E 5 **H D CHALKE**

A NEW CLINICAL ENTITY ?

SIR,—In a series of letters to your journal in the past few months, epidemics of aseptic meningitis, often associated with rubella-like exanthema, have been discussed These outbreaks have occurred mostly in England, but epidemics were also reported from Belgium and Holland, where ECHO virus type 9 has been isolated from such cases[1] In Sweden this syndrome has been very common since September, 1956

The syndrome does not appear to be altogether new Thus Gabinus[2] has described an outbreak of meningo-encephalitis combined with rubella-like exanthema in Sweden in 1946, and Parry and Good[3] reported the occurrence of a similar clinical picture in 1948 in England

The outbreaks of aseptic meningitis in Sweden during September and October, 1956, were usually not associated with a rash. However, during November and December the combination of aseptic meningitis with exanthema was much more common

The familial occurrence of cases with and without exanthema was quite typical of the outbreaks, and the clinical picture was similar to that described in your columns In about 70% of a total of 64 patients examined over the period from September to January, agents which were cytopathogenic for monkey-kidney cells and human embryonic lung cultures were isolated These were obtained from fæces, throat swabs, or cerebrospinal fluid (C S F) Virus was *found in* C S F *in* 13 cases In several cases virus was isolated from fæces, throat swabs, and C S F from the same patient Fæcal extracts inoculated into suckling mice did not provoke symptoms On the other hand the cytopathogenic agents produced flaccid paralyses in suckling mice in 7 of 20 isolations examined thus far after one or two passages in tissue culture The virus was neutralised in tissue culture by ECHO type 9 antiserum, which type was found in association with the above mentioned syndrome in an outbreak described by Crawford et al[4,5] during an outbreak in England in 1954 In the majority of our cases examined there was a distinct increase of antibody titre against ECHO type 9 virus during the acute phase of the disease

There is an indication, however, that a similar syndrome can be caused by another agent Thus in a third outbreak we have isolated a virus in approximately 65% of 20 cases examined This virus differs from ECHO type 9 *in several* ways and resembles the agent described by Neva and Enders[6] in connection with the so called Boston exanthema In 3 cases we isolated virus from the C S F One of the agents was neutralised by an anti ECHO-virus type 4 serum kindly supplied by Dr Krech, of Berne, who has isolated this type from cases of aseptic meningitis Our strain seems not to be related immunologically to the strains isolated by Neva and Enders

Stockholm, Sweden **TORSTEN JOHNSSON**

Obituary

EVARTS AMBROSE GRAHAM

M D Rush, LL D Leeds and Glasg , Hon F R C S

Prof Evarts Graham died on March 4 at the age of 73 at the Barnes Hospital, St Louis, where he had carried out much of the work on thoracic and biliary surgery which won him an international reputation A former president of the American College of Surgeons he was also an honorary fellow of the English college and he held honorary degrees from an English and a Scottish university

He was born in Chicago, where his father, *Dr David W Graham*, was a surgeon on the staff of the Presbyterian Hospital In 1900 he entered Princeton University, and after graduating in 1904 with credits in chemistry and biological sciences he began a concentrated medical course at Chicago University and Rush Medical College Before he graduated M D in 1907 he had already published his first medical paper—a joint report on generalised blastomycosis After his intern year at the Presbyterian Hospital he "withdrew from surgery," as a friend later put it, for *further* and wider studies He joined the Chicago Pathological Society, which at that time included a distinguished group of men who were studying the integration of morbid anatomy with physiology and chemistry He spent two years at the Sprague Institute for Medical Research and a further two years as a postgraduate student of chemistry at the university

The 1914–18 war brought him firmly back to clinical surgery His work for the Empyema Commission on the physiological principles that underlie methods of removing pus from the chest not only clarified the Army's problem in dealing with this complication of measles and influenza in its training camps but also charted a course for thoracic surgery in the years that followed the war But this laboratory work left Major Evarts Graham unsatisfied, and he at length persuaded the Surgeon-General to send him to France in command of an evacuation hospital After the Armistice there was a frustrating period of inactivity in a small French town, and in a moment of depression he confided to the friend with whom he shared a cramped billet over a byre "I don't know what will happen to me when I get back. I have no home, no practice no hospital or teaching position, no money" His friend replied

Graham when you get home you will be offered things n a silver tray," and his heartening prophecy came true

In 1919, after Graham's return to the United States ut before he was demobilised, the Washington University ommittee came to interview him, and the day after s discharge from the Army he arrived at St Louis o take up the Bixby chair of surgery At that time ll-time clinical chairs were an innovation, and Graham elcomed the opportunity the appointment would give m for research and teaching He planned to spend the ornings with the patients and the afternoons in the aboratory, but when he arrived at the Barnes Hospital, he teaching school of the university, he found that there ere only 40 surgical patients 'It was obvious' s he used to relate "that somebody would have to estir himself to increase the number of patients in the ain teaching hospital of the newly reorganised medical chool Somehow or other, much of that job seemed o fall on the new professor of surgery" Graham met he prejudice aroused by a hospital with a closed staff y "barnstorming trips" to county and State medical ocieties Gradually patients began to come new buildngs were soon needed, and the hospital easily met the school's need

Dr Graham's reputation and stature grew with the school till he became one of the acknowledged leaders of his specialty and his profession Of these years of achievement C F W I, a British colleague, writes

Thirty years ago when I first knew him, Evarts Graham was already a notable figure in world surgery His introduction of cholecystography had brought new interest to the diagnosis of biliary disorders while his earlier researches on empyema and his growing interest in lung cancer had earned him a wide reputation in thoracic surgery As the acknowledged leader at Barnes Hospital he had already begun to gather about him the team of young men who were later to extend the range of his influence to many medical schools throughout the country, and already he had begun the zealous advocacy of surgical research which became one of his main interests In later years he took an increasing part in the direction of surgical services and research, served on many scientific commissions and held office as chairman of the American Board of Surgery and as a regent of the American College of Surgeons.

But, important as these things are, it may well be claimed that Graham's greatest contribution was a moral one, through the impact of his powerful personality and fine example A man of high integrity and deep convictions, he expected equal standards of others, and did not hesitate to do battle with those who seemed to fall short Especially he was an unsparing critic of any deviation from a strict code of ethics

Evarts Graham will be remembered with affection and respect by the many British surgeons who, during these thirty years have visited St Louis to work under him They will remember his massive physique his deep melodious voice his slow careful speech, his warm humanity And especially they will remember with gratitude his friendliness towards this country his tolerant understanding of our way of life, and his personal kindness to every one of them

The affection and respect which he won from his British surgical visitors led to more formal contacts with' his colleagues in this country, many of whom already knew him as editor of the *Year Book of Surgery* In 1943 he was elected an honorary fellow of the Royal College of Surgeons of England, which had already the previous year, awarded him the Lister medal He did not come to this country till 1947 to receive these honours and to deliver the Lister oration, later published in the *Annals* of the college, in which he described his first pneumonectomy for malignant disease in 1933 Graham received the honorary degree of LL.D from the University of Leeds in 1951, and he also held the honorary LL.D of Glasgow University In 1953 he was president of the International Congress of Surgeons His own country was of course not behind in recognising his achievements and worth, and he was well furnished with American medals, lectureships, and degrees The admiration and warmth which lay behind these orthodox tributes could be measured by the number of friends colleagues, and students who attended a two-day scientific meeting held at St Louis in 1952 to honour him on his retirement. In his speech at this gathering, Dr Graham looked forward eagerly to further opportunities for research and to getting back "to the laboratory in the afternoons and maybe even some mornings" Unfortunately the time that was left him was short, and his contribution to the surgery of bronchial carcinoma was insufficient to save his own life

DUDLEY WILLIAM CARMALT-JONES

M.A, D.M Oxfd, F R C.P, F R.A C.P

Dr Carmalt-Jones who died on March 5 in his 83rd year, was one of that small group of physicians who early this century were using the new knowledge of physiology and bacteriology for more systematic diagnosis and treatment of disease Born in 1874, the son of T W Carmalt-Jones, F R C S.E, he was rather late in taking up the study of medicine, for going from Uppingham to Corpus Christi College, Oxford, he studied the classics as a preliminary to the medical career His clinical work was done at St Mary's Hospital Paddington, and he qualified in 1903 Almroth Wright had but recently arrived at St Mary's, where he was beginning his stimulating work on vaccine therapy Carmalt-Jones, after holding house-appointments at his own hospital and elsewhere, joined the eager band of research students whom Wright had gathered round him

He was appointed assistant physician to the Seamen's Hospital Greenwich, in 1908 and to Westminster Hospital soon after, and in 1912 he acted as dean of the Westminster Medical School In 1911 he published his *Introduction to Therapeutic Inoculation*, which embodied the principles he had learnt from Wright But, just when he seemed set for the life of a distinguished consultant in this country, the first world war broke out, and Carmalt-Jones joined up and served in France and Egypt, finishing as consulting physician to the Egyptian Expeditionary Force and a temporary colonel in the Army Medical Services In the last year of the war he changed his plans and decided to apply for the chair of systematic medicine, which was then being established at the University of Otago, Dunedin Appointed to this post, he was at first a little disappointed with the conditions under which he worked, but soon he entered into the life of the growing medical school and identified himself with its aims and aspirations so that at the end of his time as professor he declared that his election was "the greatest piece of good fortune which has ever befallen me" For twenty years he worked hard, and inculcated the principles of medicine into the minds of many generations of students. Also he gave time and thought to the affairs of the British Medical Association and of the Royal Australasian College of Physicians, of which he was vice-president

[Zenith Studio Dunedin

Carmalt-Jones was suited to the academic manner of life and probably would not have been happy in competitive consultant practice His knowledge was great and his opinions sound, but he was a little diffident in manner, he did not seek private practice but gave all his time to his professorial duties He was a ready writer, for besides the book mentioned above he produced several others of which perhaps the best known was *Elementary Medicine in Terms of Physiology* (1929) On his retirement from the professoriate he was elected emeritus professor and he occupied some of his time writing the annals of the University of Otago Medical School which contain a great deal of information about the early days of medical development in New Zealand Another pursuit during retirement was painting and in his middle 70s he still had the energy and courage to go sketching in London *coram populo* In his 30s he had joined the Athenæum and it gave him pleasure when, a few months ago, he was elected an honorary member of the club

Dr Carmalt-Jones married in 1907 Mabel, daughter of Captain F L Tottenham. She died in 1935, leaving a son and a daughter

CHARLOTTE ALICE KING

M D Lond , M R C P , D P H

Dr Alice King, late physician to the Queen Elizabeth Hospital for Children, London, died at her home in Hampstead on Jan 11 in her 77th year

She was born in Fifeshire, but her family soon moved to London and she was educated first in a day school there, and later at Exeter High School From school she went to the London School of Medicine for Women and then to the Royal Free Hospital. After graduating in 1905, she held house-posts at her teaching hospital and the New Hospital for Women, now the Elizabeth Garrett Anderson Hospital She was appointed medical registrar at the Royal Free Hospital, and worked with Dr Sydney Owen at the Queen's Hospital for Children (now, since amalgamation with the Princess Elizabeth of York Hospital, the Queen Elizabeth Hospital for Children) In 1921 she joined the staff of " The Queen's " as assistant physician, and gave the hospital whole-hearted service for 24 years She was also for a number of years on the visiting staff of the South London Hospital for Women, until she decided to confine her work to pædiatrics For many years she was secretary of " The Queen's " medical committee She was due to retire in 1940, but as the hospital's staff was depleted as the result of the war, she stayed on despite failing health and attended with unfailing regularity to give her help until the end of the war

H. M M M writes

Dr King was one of a large and closely knit family of five brothers and four sisters, and as her nephews and nieces grew up in different parts of the world she took a keen interest in their doings and achievements and they found a warm welcome from herself and her sister when they visited her home She was quiet and unassuming in manner, methodical in her work, and kindly and tolerant in her outlook Her outpatient clinics were crowded, and during the inter war years of poverty and unemployment and the disruption of the war years, her kindness and sympathy gained her affection from many of the people of East London The kindness of herself and her sister was exemplified in the warm hospitality they gave when my flat was blasted by a bomb in 1941, and two bedraggled individuals presented themselves in the small hours of the morning at their house

Alice King was a member of the London Natural History Society, and was interested in ornithology and in archæology She and her sister took much pleasure in music and were great walkers, spending many holidays together in the Lake District, or, on Sundays enjoying strenuous tramps in Surrey or Sussex

FRANCIS GEORGE FRANCE

M B Lond

Dr France, who had been a general practitioner in Bromley, Kent, for thirty years, died at his home there on Feb 22, at the age of 58 He was born at Ludlow and was always proud of his Shropshire birth and boyhood He was educated at Ludlow Grammar School and Bromsgrove School In 1917 he joined the Welch Regiment and served in France where, at the age of 19, he was severely wounded in the chest by shrapnel He was invalided from the Army, and after he had recovered from his wounds he began his medical studies at St Bartholomew's Hospital He qualified in 1924 and then, in turn, was house-physician at Brompton Hospital and resident surgical officer at Leicester Royal Infirmary

In 1926 he joined Dr McArthur in one of the oldest practices in Bromley, and practised from the house that had at one time been the Manor House of Bromley He became honorary physician to Bromley Hospital and served in this capacity until, shortly before the start of the National Health Service, the hospital was enlarged and its staffing reorganised to include visiting consultants from London

A colleague writes

Though severely handicapped by the cardiac disability left by his wounds Dr France lived an active life as a general practitioner, caring diligently and conscientiously for a wide spread practice and earning the esteem and devotion of his patients His pleasures were those of the study, and he drew lifelong enjoyment from his reading of the Greek classics, Shakespeare, Proust, and other great writers in English and French literature He played chess for his county, and he was a founder member of the Bromley chess club and later its president

Dr France leaves a widow, two daughters, and a son His elder daughter was the first woman to win an open scholarship to St Bartholomew's She has now qualified from her father's hospital, and her brother is a student there

Dr. WILLIAM STOBIE

N J E writes

Dr William Stobie had many endearing characteristics that will long be remembered by those who worked with him He had a great zest for life The activities of youth and sport of all types, but particularly rugby, were certain to engage his interest In consequence he usually had a keen following of the more energetic students and it was not surprising to find him acting as a referee in his 50th year

[illegible]

Despite his leaning towards the youthful way of life, he was essentially a traditionalist A stickler for medical etiquette, he deplored any slackness in the formal relationship both with colleagues and patients As might be expected these virtues helped to make him a good committee man, an excellent chairman, and carried him to senior honours in local authority administration, as mayor of Oxford and latterly chairman of the Oxford bench.

Always full of energy, striding along away ahead of his followers, his familiar figure with a flower in his buttonhole and his " come along, doctor " will be sadly missed

Notes and News

AGEING BUSMEN

SOME occupations offer the elderly worker a longer welcome an others As Mr Le Gros Clark in his report on ageing in dustry has already pointed out[1] a clock maker can continue make clocks long after a miner has had to leave the coal face et the miner though he can no longer hew coal may still be le to do a useful day's work These elderly men who have ven the community years of arduous physical work deserve e opportunity to change to less strenuous work in their late fties and early sixties To talk glibly of a light job is, however, ne thing, to find it seems to be another, and Mr Le Gros Clark as already shown that many of these men have great difficulty finding alternative employment

In his latest report[2] he has examined the problems of usmen, a group who for their own health and the community's afety should be encouraged to retire when they feel the pproach of old age In a group of 150 London bus drivers he ound that 38 retired between the ages of sixty and sixty four nd a further 55 at the age of sixty five when they became ligible for a pension For a group of 150 conductors the igures were 53 and 61 respectively Though some 80% of hese men left for reasons of health some of them were prepared o go on working and went in search of other jobs, but it is ncertain how many found work.

About three quarters of the men who left the buses before eaching pensionable age were given lighter work in the arages and offices of the service, but no work could be given o those who left after they were sixty-five Moreover men ransferred to light work are compulsorily retired when they each the age of sixty five, for the number of light jobs is imited and they have to make way for the next batch of men who have had to give up driving or conducting The bus service, though clearly anxious to help its elderly employees, is thus unable to provide enough lighter jobs This is a difficulty shared by most arduous occupations, and it is unfair and ineffective to leave these undertakings to meet it alone In Mr Le Gros Clark's view the problem will only be solved by " nationally widening the range of alternative jobs "

CHRONIC BRONCHITIS

LAST year the National Association for the Prevention of Tuberculosis changed its charter to include interest in other lung and heart diseases, and last December a meeting was held under its auspices at which eleven London doctors spoke Each dealt with those aspects of chronic bronchitis in which he was expert The ætiology, diagnosis, and treatment were discussed, and the consequences of the disease when social care and chest surgery are considered The lectures have now been published in a well illustrated booklet[3]

THE PUBLIC HEALTH IN LAGOS

IN former years the report of the inspector general of medical services covered the whole of Nigeria, but the division of the country into three regions, each with its own director of medical services, has meant that the report of Sir Samuel Manuwa, the chief medical adviser to the federal government, is now restricted to an account of the problems and services in the urban area of Lagos His first report[4] in the new form is a clear and far sighted account and evaluation of a complex and developing situation

Sir Samuel at once makes the important point, which must be grasped by all administrators—medical and other—that in such tropical cities the chief difficulties relate not so much to tropical diseases as to those found in large towns everywhere He classifies the major problems as provision of hospital facilities (at present almost 1000 beds for a population of 350,000, with proposals for construction involving 750 further beds), shortage of staff, tuberculosis, mental health, sanitation (water supply, slum clearance, sewage), and health education 0 5–1 0% of the population have active tuberculosis as discovered by mass radiography, and if the experience of some other African cities is a guide, this high rate may be expected to increase, though steps are being taken vigorously to control the disease An infant mortality rate of 80 8 per 1000 live births is recorded The chief causes of death at all ages are dysenteries and diarrhœas, malaria, pneumonia, cardiovascular disease, tuberculosis, malnutrition, and tetanus The federal government controls the University College Teaching Hospital, Ibadan,[5] and the Pharmacy School, Yaba, and it trains many nurses and other workers

OUTSTAYING THEIR WELCOME

DURING the period Jan 1 to Dec 15, 1956, 1289 patients were admitted to the infectious diseases wards of Neasden Hospital, as many as 739 cases were refused One reason given for this large number of refusals is the fact that many patients overstay their discharge date 677 bed days (about 1½% of the total) were lost in this way In many cases the child had been admitted from a hostel in Fulham for mothers and children, and the mother had become homeless because she was not allowed to stay there without a child Sometimes the parents were ill or vagrant or could not be traced Eventually most of the children were claimed by their parents, but a number were adopted and others placed in residential nurseries or homes In the hope of detecting such " problem cases " early, an almoner is to be employed for two and a half days a week at the hospital

PREPARATION FOR GENERAL PRACTICE

IN 1955 the University of North Carolina made a field study of the family doctor, hoping thereby to identify some of the strengths and weaknesses of the system of medical education under which he is trained According to the Rockefeller Foundation,[6] " one of the most important conclusions was that training in internal medicine for periods longer than three months, during either the internship or hospital residency of a young M D, leads to better performance in his later years as a general practitioner No other factor was found to be more consistently correlated with good performance "

University of Oxford

On March 2 the following degrees were conferred

D M—M G Ellis, M A Peyman, Sabine J Strich
B M—D H G Ogg

University of London

The title of professor of hæmatology has been conferred on Dr J V Dacie in respect of his post at the Postgraduate Medical School of London

Dr Dacie took the M B Lond from King's College Hospital in 1935 and the M R C P the following year He has held a Medical Research Council research studentship and a Will Edmonds clinical research fellowship and he has also acted as resident pathologist at King's During the war he was for a time a pathologist in the E M S and later he served in the R A M C with the rank of major In 1946 he became senior lecturer in hæmatology at the Postgraduate Medical School, and two years later was promoted to a readership In 1956 he was elected F R C P His published work includes papers on familial hæmolytic anæmia nocturnal hæmoglobinuria and blood loss in battle casualties His *Practical Hæmatology* appeared in 1950 and *The Hæmolytic Anæmias* in 1954 He is editor of the *British Journal of Hæmatology*

The title of professor of clinical endocrinology has been conferred on Dr T Russell Fraser in respect of his post at the school

Dr Fraser graduated M B with distinction at Otago in 1932 and he has held a New Zealand University travelling fellowship In 1935 he was awarded the Hallett prize and three years later a Rockefeller travelling fellowship He has also worked as a research fellow at Harvard University In 1940 he was appointed psychiatrist at Mill Hill E M S Hospital where for the next two years he was in charge of a team investigating for the Ministry of Home Security the psychiatric effects of bombing, and he reported the results in a paper to the Royal Society of Medicine In 1943 he became investigator in charge of a team for the Industrial Research Board and in 1946 he joined the staff of the Maudsley Hospital The same year he became registrar and lecturer in medicine at the Postgraduate Medical School of London and in 1947 he was appointed to a readership in medicine there He was elected F R C P in 1948 He has published papers on insulin therapy Simmonds's disease and the urinary excretion of radioiodine as a test of thyroid function

University of Liverpool

On Tuesday, March 26, at 5 15 P M, Prof B Uvnäs, of the department of pharmacology of the Karolinska Institute, Stockholm, will deliver a lecture on the sympathetic vasodilator system

Dr A Lwoff, of the Institut Pasteur, will give this lecture on Monday, April 15, at 6 P M at the Royal Institution, 21, Albemarle Street, London, W 1 The title of his lecture is The Notion of Virus

United Hospitals' Choir

The choir, conducted by Dr Buxton Orr, is to give Mozart's requiem mass at 8 30 P M on Thursday, April 4, at the Church of St George the Martyr, Queen Square, London, W C 1 Admission will be by programme (3*s* 6*d*) to be obtained from Miss J Magrath, 18, West Side, Clapham Common, S W 4

International Conference on Hepatology

This conference will be held in Perugia from June 18 to 20 under the auspices of the medical clinic of the university and its director, Prof Giorgio Dominici Further information may be had from Dr G Menghini, Clinica Medica (Policlinico), Perugia, Italy

St. John Ambulance Brigade

A weekend conference for surgeons of all ranks will be held at the Cairn Hydro Hotel Harrogate, from Friday to Sunday, May 3 to 5 Further information may be had from the surgeon in chief's department, 8, Grosvenor Crescent, London, S W 1

Association of Psychiatric Social Workers

The annual general meeting of this association is to be held at the Middlesex Hospital, London, W 1 on Saturday, March 30, at 2 30 P M, when Mr Kenneth Robinson, M P, will give his presidential address on public attitudes toward mental disorder

Royal Medico-Psychological Association

Child Psychiatry Section—A meeting of this section will be held at the Bristol Royal Hospital for Sick Children, St Michael's Hill, Bristol, 2, on Thursday, May 2, at 5 30 P M when Dr Gaynor Lacey will open a discussion on young children with recurrent abdominal pains

Instruments used in Industrial Hygiene

The British Occupational Hygiene Society is holding a *conference on this subject* in London on April 16 and 17 It is open to non members, and further particulars may be had from Dr D Turner, M R C Laboratories, Holly Hill, Hampstead, N W 3

Medical Society of London

At the 177th anniversary dinner on March 7, Lord Evershed remarked that the society's early records included no mention of the Napoleonic wars on land or at sea, yet perhaps this was not so singular, for in the whole of Shakespeare's works there figured but one Spaniard—and he a fantastical figure Lord Evershed was convinced that his friend the president (Dr T C Hunt) would soon be making fun of the law, and for his own part he recalled *Voltaire's definition of* a physician as one who pours drugs of which he knows little into bodies of which he knows less Replying for The Society, the President likened Lord Evershed's *life as Master of the Rolls to that of* a consultant in John Lettsom's day, when the apothecaries brought news of cases to him in a coffee house Nowadays of course the news came from Savile Row, usually gently through *Prescribers Notes*, but occasionally in harsher tones Turning to the society's affairs, the President said that the number of fellows had increased to nearly 700, and the society's rooms were proving too small The subscription had remained at 2 guineas for many years, indeed it had no more than doubled since Lettsom's time Dr J S Richardson dealt kindly with The Guests, and Dr Macdonald Critchley, though himself a fellow, responded as master of the Society of Apothecaries, observing without rancour that, whereas this year he was seated among the mighty, next year he would be in the body of the hall among the scornful

C M F /M E F. Physicians' Dinner

This dinner will be held at Simpson's in the Strand London, W C 2, on Saturday, March 30 Particulars can b had from Dr Arthur Willcox, 59, Harley Street, W 1

Doctors who wish to watch the Boat Race on March 30 from the Bemax premises should make early application to Dept B E J Vitamins Limited, Upper Mall, London W 6

THROMBOPHLEBITIS FOLLOWING INTRAVENOUS INFUSIONS · TRIAL OF PLASTIC AND RED RUBBER GIVING-SETS

REPORT TO THE MEDICAL RESEARCH COUNCIL BY A SUBCOMMITTEE* OF THE COUNCIL'S BLOOD TRANSFUSION RESEARCH COMMITTEE

THROMBOPHLEBITIS is a common complication of continuous intravenous infusions and, though rarely dangerous, may cause the patient much pain and discomfort Recent reports, summarised in table I, show that when infusions given through standard National Blood Transfusion Service sets are continued for more than twelve hours the incidence of thrombophlebitis is over 50%

In 1953 the frequent occurrence of thrombophlebitis after intravenous infusions was considered by the Blood Transfusion Research Committee of the Medical Research Council The work of Handfield-Jones and Lewis (1952) had shown that the incidence of thrombophlebitis varies with the type of rubber tubing used in the making of intravenous drip sets Pure latex rubber tubing was associated with the lowest incidence It was decided to carry out tests with sets made of plastic tubing as it seemed likely that this tubing would be associated with a lower incidence of thrombophlebitis As soon as a plastic set manufactured in Britain became available, a subcommittee was formed to carry out the tests, and the present report summarises the findings of this subcommittee

Methods

The Plastic Transfusion Set

The tubing of the set used in the trials was made of polyvinyl chloride with added "plasticiser" and "stabiliser" The set consisted of a nylon piercing-needle, a filter chamber with a nylon mesh filter, a drip-chamber, a length of plastic tubing (approximately 6 feet) terminating in a short length (3 in) of latex rubber tubing, and an adapter fitting into a needle or cannula

TABLE I—INCIDENCE OF THROMBOPHLEBITIS FOLLOWING INTRAVENOUS INFUSIONS LASTING MORE THAN 12 HOURS, ADMINISTERED THROUGH BLOOD TRANSFUSION SERVICE RED RUBBER GIVING SETS

Article	No of cases	No reaction	Thrombophlebitis	
			No of cases	% of total
Bolton Carter 1951a	32	11	21	66

Page et al 1952	29	10	19	65
Jones 1954	26	7	19	73
Present series 1956	189	84	105	56

The set was used in conjunction with a special rubber bung incorporating an air inlet valve

Sterility, pyrogen, and toxicity tests carried out on sample sets were all negative

Thrombophlebitis Trial

The particular object of the subcommittee was to ascertain the incidence of thrombophlebitis when the set was used for continuous intravenous infusions It was decided to make a direct comparison between plastic and red rubber giving sets as this would at once give a standard of comparison for the results and also eliminate the influence of unknown factors which might operate with different techniques in different hospitals The red rubber sets used in this trial were those being supplied in 1956 by the National Blood Transfusion Service

Seven hospitals took part in this trial Several methods were used to ensure random use of a rubber or plastic set Thus, in one hospital, the choice of set depended on the day of admission, in other hospitals it depended on whether the patient's hospital number was odd or even, and in others the type of set was alternated between consecutive cases When a patient received more than one infusion, only the results of the first were included

TABLE II—FREQUENCY DISTRIBUTION OF LENGTH OF INFUSION AT EACH CENTRE FOR THE TWO TYPES OF SET *

—	Centre	Length of infusion (hours)

* The various centres participating in the trial are indicated by initial letters H = Hammersmith Hospital St T = St Thomas's Hospital R I E = Royal Infirmary, Edinburgh S = Southmead Hospital M = Middlesex Hospital, R I M = Royal Infirmary Manchester B = Birmingham Accident Hospital

Workers in the "thrombophlebitis trial" also reported on the performance of the set, and further reports were obtained from 13 other civil and many service hospitals These reports, totalling over 700, have been used in working out a revised design Plans for the manufacture of this modified set are going forward, but the set is not yet in production

Recording of Results

Infusions were set up in the ordinary way by housemen and registrars In each centre one, or at most two, individuals undertook to make all observations and these were recorded on a special card The details noted were the times at which the infusion was begun and discontinued, the type of needle or cannula used, the site and method of insertion into the vein, and the nature and amount of fluid or fluids given Detailed information was sought on the local reaction to the infusion This was assessed by measuring the length of vein thrombosed

6969

or inflamed The presence of any perivenous œdema and the degree of tenderness were also recorded This method of recording has allowed the results to be divided into four categories, as follows

"O"—No reaction, or painless thrombosis without inflammation

"M"—Mild reaction, with less than 3 in of vein inflamed.

"S"—Severe thrombophlebitis, affecting 3 to 6 in. of vein.

"S+"—Extensive thrombophlebitis, affecting more than 6 in of vein

Results

428 cards were suitable for analysis A further 24 record cards were found to be unsuitable either because the infusion had been given into a great vein, or because insufficient details were supplied, or because the patient had died before the results of infusion could be assessed

The durations of the infusions in the 428 cases suitable for analysis are set out in table II In 52 cases the infusion lasted for exactly twelve hours, and in 7 for less than twelve hours Since thrombophlebitis did not occur among these 59, they are not considered further in this paper Table II shows that approximately the same number of infusions lasting from thirteen to forty-seven hours were given through plastic and rubber sets, but that rubber sets were used a little more commonly for infusions lasting forty-eight hours or more this is presumably due to chance A review of the record cards shows that blood, normal saline, and either 4 3% dextrose with 0 18% saline or 5% dextrose were given to almost all patients There was no significant difference in the nature or amount of fluid given to the patients in the two series Very few patients received blood only, so it is not possible to compare the incidence of thrombophlebitis in patients receiving blood-transfusions with that in patients receiving only crystalloid solutions

The distribution of reactions for each type of transfusion equipment, in infusions lasting more than twelve hours, is shown in table III The proportions of positive reactions (adding together the categories S+, S, and M) are 57 out of 180 (32%) for the plastic sets and 105 out of 189 (56%) for the rubber sets The difference (24%) between these two percentages has a standard error of 5% and is thus highly significant The probability of exceeding this difference by chance is less than 10^{-5} The proportions of very severe and severe reactions (S+ and S) are 32 out of 180 (18%) for the plastic sets, and 64 out of 189 (34%) for the rubber sets The difference between the two percentages is 16% with a standard error of 5%, a value significant at a probability of less than 10^{-3}

Thus there can be no doubt that in the centres taking part in this trial, and for the types of infusion performed, use of the plastic sets on the average considerably reduced the incidence of thrombophlebitis

It is of some interest to examine the results separately for each centre and for various lengths of infusion

TABLE IV—FREQUENCY DISTRIBUTION OF REACTIONS WITH THE TWO TYPES OF SET, AT DIFFERENT CENTRES, FOR INFUSIONS LASTING MORE THAN 12 HOURS*

—	Reaction	Centre							Total
		H	St T	R I E	S	M	R I V	B

TABLE V—FREQUENCY DISTRIBUTION OF REACTIONS WITH THE TWO TYPES OF SET FOR VARIOUS LENGTHS OF INFUSION

—	Reaction	Length of infusion (hours)						Total
		13–23		24–47		48 or more		
		No	%	No	%	No	%	
Plastic	S+	0	0	3	4	6	12	9
	S	2	3	9	13	12	24	23
	M	6	10	13	19	6	12	25
	O	55	87	42	63	26	52	123
	Total	63	100	67	99	50	100	180
Rubber	S+	2	4	9	14	14	21	25
	S	9	16	9	14	21	32	39
	M	4	7	18	27	19	29	41
	O	42	74	30	45	12	18	84
	Total	57	101	66	100	66	100	189

Tables IV and V show the distributions of reactions subdivided by centre and length of infusion respectively Table IV shows that the incidence and severity of thrombophlebitis, with either set, varied considerably from one centre to another, and also that evidence for the superiority of the plastic set is very strong in some centres but lacking in others In a further analysis, the incidence of thrombophlebitis for the two sets at each centre was compared, allowance being made for possible differences in the lengths of infusions with the two sets (In this calculation the Manchester and Birmingham centres were pooled because of the small numbers involved) The plastic set gave a significantly lower incidence of thrombophlebitis than the rubber (at the 5% level of significance) at Hammersmith and the Middlesex Hospitals, and in the pooled results from Manchester and Birmingham In no centre was the rubber set significantly better

Similarly, table V shows that the incidence and severity of thrombophlebitis increased appreciably with the length of infusion, for each set, and that the superiority of the plastic set is apparent in each of the three length-of-infusion groups A further analysis, allowing for the different incidence at each centre, confirms that the contrast between the two sets reaches the 5% level of significance for each length of infusion

Discussion

This trial again shows the high incidence of thrombophlebitis when prolonged intravenous infusions are given through red rubber sets It also provides clear evidence that the incidence of thrombophlebitis is much lower when plastic tubing is used The fact that the incidence of major thrombophlebitis (categories S and S+) was nevertheless as high as 18% when plastic tubing was used calls for some comment Most of the patients in this trial received autoclaved glucose solutions which are known to be acid (Todd 1951), many patients also received injections of drugs into the tubing of the sets It may well be that both these factors cause some injury to the veins It would thus be unwise to conclude that the cases of major thrombophlebitis following infusions through plastic tubing were necessarily due to harmful substances contained in the tubing

The work of Bolton Carter (1951b) firmly established the importance of the period of infusion in influencing the incidence of thrombophlebitis The present observations confirm this finding and show that in infusions lasting twelve hours or less the incidence of thrombophlebitis is negligible

Summary

The incidence of thrombophlebitis following long continued intravenous infusions has been assessed in two series of recipients In one series the infusions were given through red rubber sets, as supplied by the National

Blood Transfusion Service, in the second series the infusions were given through sets made of plastic In other respects the two series were closely comparable In the series in which plastic tubing was used, the incidence of thrombophlebitis was approximately half of that in which red rubber tubing was used

The subcommittee wishes to express its thanks to all those physicians and surgeons who readily gave permission for this trial to be conducted in their wards The plastic set used in this trial was developed and manufactured by Messrs Capon Heaton & Co, of Birmingham Their representative, Mr A Boot, gave the members of the subcommittee great assistance in the design of the set and they record their appreciation of his ready help

FRACTURES OF THE FEMORAL NECK

REVIEW OF MANAGEMENT AND RESULTS

D B Murray
L R C P.E, D A
REGISTRAR, DEPARTMENT OF ANÆSTHESIA

Stuart Young
M.A Camb, M B Glasg, F R F P S
SENIOR REGISTRAR, DEPARTMENT OF SURGERY,
SOUTHERN GENERAL HOSPITAL, GLASGOW

This is a review of the 204 recent fractures of the femoral neck admitted to the general surgical unit of the Southern General Hospital, Glasgow, in 1948–55

There was no selection of cases, many being directed to the hospital by the local admission bureau Patients were admitted from their own homes, from local lodging-houses, from a geriatric home, from a local mental hospital, or, when the accident happened out-of-doors, direct by ambulance When the accident was in the patient's home, there was often delay in seeking medical attention, particularly if the patient had been living alone 20 patients came from the West of Scotland and the Western Isles They were transferred to Glasgow either by road or by air, sometimes several days after their accident When admission to hospital was delayed for any reason, patients were often in a very poor general condition—medically, nutritionally, and mentally In some, early bedsores and hypostatic pneumonia were already apparent

General Condition of Patients

Medical assessment revealed that about 90% of patients over the age of 65 had emphysema, generalised arteriosclerosis, and hypertension, more than 60% had chronic bronchitis, and 16% had bronchiectasis Many suffered from malnutrition and most showed some anæmia in more than 20% to a marked degree Degenerative myocarditis was diagnosed in 60% of the cases and 12% had recent or old myocardial infarction In 44% electrocardiography showed left ventricular strain and/or coronary insufficiency Urinary infection was present in 30% of cases

The patient was assessed by the surgeon and the anæsthetist, between whom lay the decision to offer or withhold operation

The age of patients ranged from 7 to 95 (average 71) 20 patients were under the age of 50 and 12 of these had been involved in either an industrial or a road accident Of the 7 mental patients only 1 was over the age of 60 their average age being 55 There were 125 females and 79 males

Ætiology

Two fractures occurred indoors for every one out-of-doors, and of those which occurred out-of-doors half were caused by street accidents or by industrial accidents 44 patients reported a feeling of dizziness before falling

The hospital records were not always explicit as to the actual cause or the mode of production of the fracture The most frequent indoor causes were (*a*) falling out of bed (18 cases), (*b*) falling on a stairway (11 cases), (*c*) tripping over a carpet (7 cases), and (*d*) falling off a chair or a box (6 cases) The most frequent outdoor causes were (*a*) road accidents involving a vehicle (11 cases), (*b*) jumping off a tram or bus (8 cases, including 5 patients over 80 and 1 over 90), (*c*) direct trauma at work (7 cases), (*d*) falling from a height (5 cases), (*e*) tripping on an uneven road (4 cases), (*f*) falling on an icy road (4 cases), and (*g*) slipping on a wet street (3 cases)

The peak periods of the year were May and October–December

Bone changes seen on X-ray examination were osteoporosis, osteitis deformans, osteitis fibrosa cystica, and metastasis in bone Arthritis of the hip-joint was often present The part played by lack of mobility at the hip-joint must not be underestimated

Site of Fracture

For simplicity, the fractures have been classified as transcervical (intracapsular) and trochanteric (extracapsular) There were 91 transcervical fractures (average age 70) and 113 trochanteric fractures (average age 72) Fracture of the right femoral neck was as common as fracture of the left femoral neck 3 patients had their two femoral necks fractured on different occasions, the level of fracture was the same each time, being transcervical in 2 cases and trochanteric in 1

Treatment

Table I shows the number of recent fractures of the femoral neck admitted during the years under review together with the method of treatment Of the 204 cases 139 were treated by operative fixation and 65 conservatively

TABLE I—TREATMENT OF FRACTURE OF FEMORAL NECK

Year	Operation	Conservative	Total
1948	3	9	12
1949	4	11	15
1950	4	3	7
1951	10	11	21
1952	19	9	28
1953	28	9	37
1954	35	4	39
1955	36	9	45
Total	139	65	204

Conservative Treatment

In the elderly patient the conservative treatment of choice was Hamilton-Russell traction, in the young patient extension in a Thomas splint was used Occasionally, when impaction appeared secure and hip movements were painless, freedom without weight-bearing was allowed In 1948–51 61% of all the cases were treated conservatively, but in 1952–55 only 20%

Unfit for operative treatment (32 cases, 28 deaths)—Of all the cases admitted in 1948–51 17 (30 8%) were in this group, and in 1951–55 15 (10%) The difference (20%) between the two periods probably reflects a change in the standard accepted for operation in the more recent period 4 patients, aged 80, 83, 87, and 87, were moribund on admission, they were poorly nourished and personally neglected, had chronic medical conditions, and were hypotensive and shocked, they did not respond to resuscitation, including blood-transfusion, and died within twenty-four hours of admission.

Treated conservatively although fit for operation (33 cases, 3 deaths).—Conservative treatment was the method of choice in 31 of these cases. It was enforced in the 2 remaining cases where, because of inability to pass a guide wire through a dense femoral neck and because of failure to get an acceptable reduction, operation was abandoned. Of all the cases admitted in 1948–51 17 (31·5%) were in this group, and in 1952–55 16 (10·7%). In the former period trochanteric fractures were usually treated conservatively, as were patients with impacted transcervical fractures if in an acceptable position. In the latter period a small minority were treated conservatively for the following reasons: (1) impaction of transcervical fracture, (2) gross comminution of trochanteric fracture, (3) greenstick fracture, and (4) because nailing was abandoned.

Operative Treatment

Of the 139 cases treated by operation a Smith-Petersen nail was inserted into 63 transcervical fractures and 2 trochanteric fractures, and a McLaughlin nail and plate was applied to 74 trochanteric fractures. These 139 cases may be divided according to whether operation was the primary or the secondary choice.

Primary choice (129 cases, 26 deaths).—The average period of delay after fracture was four days. Normally the operation was done at one of two regular operating sessions during the week, usually from two to seven days after admission of the patient to hospital. Associated with the medical survey, treatment was initiated when necessary, a transfusion given when required, and the skin of the operation site prepared.

Secondary choice (10 cases, 10 deaths).—The average period of delay was eighteen days. Initially turned down as completely unfit for operation these patients showed no improvement up to the seventh day or thereafter. When, for various reasons, nailing was eventually done, 2 died the day after operation, 1 on the third day, 3 after a fortnight, 1 at three weeks, 2 in the second month, and 1 after four months.

The approach was always through an adequate lateral incision, and nailing was controlled by radiography. The operating-time—i.e., from induction when general anæsthesia was used—was usually between sixty and ninety minutes but was occasionally prolonged by technical difficulties.

Premedication

Several combinations of drugs were used:

(a) Morphine sulphate and atropine sulphate.
(b) Pethidine hydrochloride and atropine sulphate.
(c) The hydrochlorides of chlorpromazine, promethazine, and pethidine.

Although each combination produced the desired sedative effect, respiratory depression and hypotension subsequent to the administration of morphine sulphate, usually gr $^1/_6$, made morphine and atropine less acceptable than pethidine and atropine, particularly when general anæsthesia followed. The "lytic cocktail" (chlorpromazine, promethazine, and pethidine) was exhibited because of its reputed ability to protect from stress, particularly from hæmorrhage and trauma, but it often caused a preoperative fall in blood pressure.

To prevent preoperative hypotension and to maintain the blood-pressure during operation two vasopressor drugs were used: methylamphetamine hydrochloride ('Methedrine') and mephentermine sulphate ('Mephine' sulphate). The latter, besides being a stronger vasopressor than methylamphetamine hydrochloride, had a longer action.

Analgesia

During operation it is very important to avoid anoxia. To this end careful attention was paid to providing enough oxygen, to replacing blood-loss, and to supporting the blood-pressure with drugs. In this respect mephentermine sulphate again proved most useful.

Analgesia was provided by:

(1) General anæsthesia: thiopentone sodium, nitrous oxide, oxygen, and pethidine hydrochloride.

(2) General anæsthesia and local analgesia: as above together with the local injection of 1% lignocaine hydrochloride.

(3) Local and general analgesia: 1% lignocaine hydrochloride and pethidine hydrochloride.

Although the operation can mostly be done under light general anæsthesia, difficulty may arise in manipulation of the fracture. To facilitate the manipulation deeper anæsthesia may be required for a short time, or a short-acting muscle relaxant may be used. This is a stage, however, during which the patient may become hypotensive. Recovery of the blood-pressure may then be slow, and it may be difficult to sustain it at the preoperative level.

In this series the least general postoperative upset in the elderly patient was associated with the use of local plus general analgesia produced by local infiltration with 1% lignocaine hydrochloride 100 ml. and intravenous pethidine hydrochloride 25–100 mg. Oxygen inhalations were only given when thought necessary. With patience, difficulty in reducing most fractures can be overcome without resorting to general anæsthesia or to muscle relaxants. The technique has the virtue of simplicity in application and permits the anæsthetist to concentrate on looking after the patient's general condition.

Postoperative Care

During the last two years under review, preference for postoperative sedation has been for paraldehyde and pethidine hydrochloride, the latter being administered only when there was a complaint of pain. In the more recent cases, if signs of cerebral upset were present chlorpromazine hydrochloride was given. Chlorpromazine hydrochloride was not used as an occasional sedative in any of the cases, but, used specifically in association with mental disturbance, it gave a favourable impression.

After operation, medical treatment was continued where necessary. Special emphasis was placed on an adequate diet and an adequate intake of fluids. Patients were usually sitting in a chair within forty-eight hours, and they had daily hip and knee exercises. When they were considered fit enough they were encouraged to move about the ward on crutches. Those who became proficient were allowed home and returned to the outpatient department for regular review. Non-weight-bearing was usually continued for twelve weeks, and few patients, unless ambulant on crutches, got home before this time. If radiography did not definitely confirm union weight-bearing was further postponed.

RESULTS

Mortality

Of the 204 patients 67 (29 males and 38 females) died in hospital—an overall mortality of 33%.

Of those operated on (139) the operative mortality, covering the arbitrary period of twenty-eight days after

TABLE II—MORTALITY IN RELATION TO TREATMENT OF FRACTURE OF FEMORAL NECK

* Including 4 deaths in first week

† Including 6 (including 4 in first 48 hr)

Table V shows these 127 patients classified according to the capabilities without reference to their previous condition and based on the following requirements

Group A: return to full mobility, requiring no support, although a slight limp might be present. In the case of the younger patients return to full employment

Group B. Mobile and able to do their own shopping but feeling they required a stick for support

Group C Mobile but requiring the support of one or two sticks and leading an indoor existence

Group D: Unable to walk, spending most of their time in bed

All cases of non-union are found in groups C or D except 5 transcervical fractures classified in group B, 1 was a fracture in an amputation stump, and in 4 there was fibrous union in good position

There were 19 cases of non-union (table VI) 16 transcervical and 3 trochanteric fractures In the absence of radiography or precise radiological reports the outcome was doubtful in 20 cases

Discussion

It is doubtful whether the mortality-rate deserves the importance usually accorded it when the results of treatment of fracture of the femoral neck are being discussed. Indeed, perusal of the literature suggests that comparison of the results obtained in different series is of only limited value The variation in age and possibly also in the physical condition of patients contributes to this, whilst lack of uniformity in the duration of the follow-up tends to be misleading when results are interpreted Here we take the view that the general and mental condition of patients who do survive is worthy of greater consideration sharing equal importance with the recovery of function of the injured limb

The problems associated with fractures of the upper end of the femur in the elderly fall into two categories—orthopædic and geriatric Besides the patient's medical condition, other factors must strongly influence the decision to offer or withhold operation The transcervical fracture with displacement requires manipulation and internal fixation to maintain position and attain union The trochanteric fracture, however allows greater latitude in treatment Equally good results are reported from operation (Evans 1951) and from conservative treatment (Murray and Frew 1949) The remaining factors which influence the decision in favour of operation are (1) greater comfort and mobility for the patient, (2) greater facility for nursing and (3) bed economy The third factor, for reasons given below, we consider to be not in the patient's best interest

TABLE VI—ASSESSMENT OF UNION

Treatment	Transcervical fracture			Trochanteric fracture		
	Union	Non-union	?	Union	Non-union	?
Operation	30	9	9	49	2	4
Conservative	7	7	4	12	1	3
Total	37	16	13	61	3	7

The management of each case requires adjustment to obtain the greatest benefit for the patient, especially the poor risk patient. Prominent among the questions thus raised is the urgency of operation. Evans (1953) respond to resuscitation, including blood-transfusion, and died within twenty-four hours of admission

Treated conservatively although fit for operation (33 cases, 3 deaths) —Conservative treatment was the method of choice in 31 of these cases It was enforced in the 2 remaining cases where, because of inability to pass a guide wire through a dense femoral neck and because of failure to get an acceptable reduction, operation was abandoned Of all the cases admitted in 1948–51 17 (31 5%) were in this group, and in 1952–55 16 (10 7 %) In the former period trochanteric fractures were usually treated conservatively, as were patients with impacted transcervical fractures if in an acceptable position In the latter period a small minority were treated conservatively for the following reasons (1) impaction of transcervical fracture, (2) gross comminution of trochanteric fracture, (3) greenstick fracture, and (4) because nailing was abandoned

Operative Treatment

Of the 139 cases treated by operation a Smith-Petersen nail was inserted into 63 transcervical fractures and 2 trochanteric fractures, and a McLaughlin nail and plate was applied to 74 trochanteric fractures These 139 cases may be divided according to whether operation was the primary or the secondary choice

Primary choice (129 cases, 26 deaths) —The average period of delay after fracture was four days Normally the operation was done at one of two regular operating sessions during the week, usually from two to seven days after admission of the patient to hospital Associated with the medical survey, treatment was initiated when necessary, a transfusion given when required, and the skin of the operation site prepared

Secondary choice (10 cases, 10 deaths) —The average period of delay was eighteen days Initially turned down as completely unfit for operation these patients showed no improvement up to the seventh day or thereafter When, for various reasons, nailing was eventually done, 2 died the day after operation, 1 on the third day, 3 after a fortnight, 1 at three weeks, 2 in the second month, and 1 after four months

The approach was always through an adequate lateral incision, and nailing was controlled by radiography The operating-time—i e , from induction when general anæsthesia was used—was usually between sixty and ninety minutes but was occasionally prolonged by technical difficulties

Premedication

Several combinations of drugs were used

(*a*) Morphine sulphate and atropine sulphate
(*b*) Pethidine hydrochloride and atropine sulphate
(*c*) The hydrochlorides of chlorpromazine, promethazine, and pethidine

Although each combination produced the desired sedative effect, respiratory depression and hypotension subsequent to the administration of morphine sulphate, usually gr $^1/_6$, made morphine and atropine less acceptable than pethidine and atropine, particularly when general anæsthesia followed The "lytic cocktail" (chlorpromazine, promethazine, and pethidine) was exhibited because of its reputed ability to protect from stress, particularly from hæmorrhage and trauma, but it often caused a preoperative fall in blood-pressure

To prevent preoperative hypotension and to maintain the blood-pressure during operation two vasopressor drugs were used methylamphetamine hydrochloride ('Methedrine') and mephentermine sulphate ('Mephine' sulphate) The latter, besides being a stronger vasopressor than methylamphetamine hydrochloride, had a longer action

Analgesia

During operation it is very important to avoid anoxia To this end careful attention was paid to providing enough oxygen, to replacing blood-loss, and to supporting the blood-pressure with drugs In this respect mephentermine sulphate again proved most useful

Analgesia was provided by

(1) General anæsthesia thiopentone sodium, nitrous oxide, oxygen, and pethidine hydrochloride

(2) General anæsthesia and local analgesia as above together with the local injection of 1% lignocaine hydrochloride

(3) Local and general analgesia 1% lignocaine hydrochloride and pethidine hydrochloride

Although the operation can mostly be done under light general anæsthesia, difficulty may arise in manipulation of the fracture To facilitate the manipulation deeper anæsthesia may be required for a short time, or a short acting muscle relaxant may be used *This is a* stage, however, during which the patient may become hypotensive Recovery of the blood-pressure may then be slow, and it may be difficult to sustain it at the *preoperative level*

In this series the least general postoperative upset in the elderly patient was associated with the use of local plus general analgesia produced by local infiltration with 1% lignocaine hydrochloride 100 ml and intravenous pethidine hydrochloride 25–100 *mg* Oxygen inhalations were only given when thought necessary With patience, difficulty in reducing most fractures can be overcome without resorting to general anæsthesia or to muscle relaxants The technique has the virtue of simplicity in application and permits the anæsthetist to concentrate on looking after the patient's *general* condition

Postoperative Care

During the last two years under review, preference for postoperative sedation has been for paraldehyde and pethidine hydrochloride, the latter being administered only when there was a complaint of pain In the more recent cases, if signs of cerebral upset were present chlorpromazine hydrochloride was given Chlorpromazine hydrochloride was not used as an occasional sedative in any of the cases, but, used *specifically in* association with mental disturbance, it gave a *favourable* impression

After operation, medical treatment was *continued* where necessary Special emphasis was placed on an adequate diet and an adequate intake of fluids Patients were usually sitting in a chair within forty eight hours, and they had daily hip and knee exercises When they were considered fit enough they were encouraged to move about the ward on crutches Those who became *proficient* were allowed home and returned to the outpatient department for regular review Non-weight bearing was usually continued for twelve weeks, and few patients unless ambulant on crutches, got home before this time If radiography did not *definitely confirm union*, weight-bearing was further postponed

Total	37	16	13	61	3	7

The management of each case requires adjustment to obtain the greatest benefit for the patient, especially the poor-risk patient Prominent among the questions thus raised is the urgency of operation. Evans (1953) points out that patients over the age of 70 do not tolerate pain and enforced immobility well and are quick to become irrational and incontinent. He therefore advocates emergency operation in trochanteric fractures. Having thus relieved pain and restored mobility, he proceeds with any medical treatment that may be considered necessary. On the other hand, McElvenny (1949) says "It must be definitely and emphatically stated that an intracapsular fracture of a femoral neck in an elderly patient is no surgical emergency, but may well be a *medical* emergency," and advocates a complete survey of the vital functions and systems.

In view of the average age and usual medical condition of the patients with transcervical and trochanteric fractures in this series, the latter approach to the problem has seemed to us the more logical, because each case is thus considered individually, from the time of admission, not only from the orthopædic but also from the medical standpoint. Relief from pain is important (Evans 1953) and can be achieved by operation, but patients do get relief from pain under extension and also benefit from rest before operation. Preliminary treatment by extension allows the medical survey and treatment to be instituted and adequate skin preparation of the operation site can be carried out.

In the last two years under review it was usual for forty-eight hours to elapse before operation, even in patients in whom there were no medical or surgical reasons for delaying operation. This was prolonged up to seven days if benefit could be expected from medical treatment, with special reference to ketosis, dehydration, secondary anæmia, reduced blood volume, threatened cardiac failure, and urinary infection. Delay longer than seven days, however, was not thought advisable when operation was the primary choice. When operation was the secondary choice and was performed after this period, the mortality was high.

With reference to the preoperative medical survey we agree with Gavey (1953), that "too much medical investigation in these old people may lead to unwarranted delay in getting on with the job." On the other hand, we regard adequate preparation for operation as a prerequisite in the prophylaxis of mental disturbance and in maintaining the general condition. Allison (1952) states that the recognised causes of cerebral upset are dehydration, alkalosis, and anoxia. These conditions are often present in these aged patients and may also be associated with trauma and operation under general anæsthesia. Preoperative treatment directed to correct such deficiencies will contribute to the avoidance of circulatory failure, thus helping to guard against a general effect (shock) and the direct effect on cerebral metabolism which contributes to mental confusion. Even when the operation is performed under local analgesia, therefore, attention to these points is important.

The onset of mental confusion after operation has so far not been seen when local plus general analgesia has been used. It was, on the other hand, fairly common after general anæsthesia. Mental upset when it occurred was of ominous significance, especially if associated with incontinence. As regards the avoidance of postoperative mental disturbance the sustaining effect of the vasopressor drugs, notably mephentermine sulphate, appears to be of value. It is, of course, axiomatic that, no matter what method of producing analgesia is used, meticulous attention should be paid to transfusion, as regards both replacing blood loss and avoiding overloading of the cardiovascular system.

After operation strict supervision of sedation was directed to the avoidance of mental confusion. Bedford (1955) notes that, when postoperative confusion appears in old people, the vicious circle of hypnotics, confusion, and more hypnotics must be avoided. The retention of full mental acuity and morale in these patients into the postoperative period ensures cooperation as regards nourishment, exercises, and ambulation. Without this cooperation great difficulty is experienced in attaining good function.

As reported above, patients treated by operation were usually up in a chair within forty-eight hours and had supervised exercises for their knees and hips from the morning after operation. Those in good physical condition and unimpaired mentally responded well to such treatment and quickly mastered the use of crutches. Such patients, when sufficiently adept and allowed home, could usually be trusted to remain mobile. The functional result with weight-bearing was usually good. The remainder, most of the patients in this series, required supervision in hospital. Too weak physically, they required continued medical treatment, or, lacking moral strength, they required to be coaxed at every stage and even beyond the stage of starting weight-bearing. In these cases continued leg exercises during the non-ambulant phase and instruction in walking when weight-bearing begins are important. Once fully ambulant and self-reliant, patients usually wish to remain so. To allow many of these patients home before this stage is reached would be to disregard the human factor and the fact that they often require the incentive of the hospital routine to maintain progress; otherwise the patient may lose interest or decide to rely wholly on relatives. Bed economy would be attained at the price of poor function.

Stewart (1955) notes that "some aged patients progressed less well after return home, for no other apparent reason than that discharge from hospital removed the only remaining incentive to the will to live." This was borne out in this series in the few who were discharged without crutches in the preambulant stage, in contrast to those who were sufficiently ambulant to be self-reliant before discharge. We therefore believe that hospital treatment should be continued in most cases until the patient is ambulant and has regained self-reliance.

Conclusions

If a patient with a fracture of the femoral neck is to derive maximum benefit from operation, as much attention must be paid to maintaining the general and mental condition as to factors influencing the functional result. To this end each patient should receive individual consideration from the time of admission.

An emergency operation does not appear to be indicated. Where an operation is the primary choice, however, the best time for it probably lies between forty-eight hours and seven days after the fracture was sustained.

Local and general analgesia are more satisfactory than general anæsthesia, so far as maintaining the patient's condition is concerned; adequate reduction can be achieved under local and general analgesia.

Hospital treatment of the aged patient with a fracture of the femoral neck should be continued until the patient is ambulant and self-reliant. The incentive of the hospital routine is often necessary to achieve good functional results.

Summary

All recent fractures of the femoral neck admitted to the Southern General Hospital, Glasgow, in 1948–55 are reviewed.

The management of these patients from the time of admission until they are ambulant and self-reliant is discussed.

The importance of the hospital routine in attaining a good functional result is emphasised.

We are indebted to Mr. R. B. Wright, senior surgeon, Southern General Hospital, for encouragement and constructive criticism. We also wish to thank Miss A. MacLean for secretarial help.

AN increasing number of synthetic antispasmodic agents are being produced, mainly for use in spastic disorders of the gastro intestinal tract These agents have many of the actions of atropine and as such may be of value as mydriatics or cycloplegics Eight such substances, varying considerably in toxicity and chemical structure, were investigated experimentally in the rabbit to assess their suitability for clinical use as drops or as subconjunctival injections One of these substances, oxyphenonium bromide in 5% solution, has been discussed by Fraser (1956)

Experimental Data

Of the eight agents investigated in the rabbit (table I) the tolerated systemic dose in man was not known for the two experimental substances no 4075 and no 2515 Both these could, however, be excluded from further trial because, with the greatest possible concentration for the one and the greatest tolerated concentration for the other, no adequate mydriasis was obtained The six remaining agents fell into two distinct groups (1) local tolerance was the limiting factor in the case of adiphenine hydrochloride, propantheline bromide, and tricyclamol chloride, and (2) in the remaining three—scopolamine butylbromide, oxyphenonium bromide, and penthienate bromide—the limiting factor was a low systemic dose limiting the maximal concentration explored, for the full systemic dose was contained in four drops (two drops each eye)

Table I shows that, in the largest permissible dosages, adiphenine hydrochloride and propantheline bromide were the least, and penthienate bromide the most, promising as mydriatics Four substances were therefore carried forward for clinical trial.

Clinical Observations

Tolerance and Efficacy of Penthienate Bromide

Table II shows that penthienate bromide was the most effective of the four agents selected for clinical trial In efficacy and persistence penthienate bromide 2% drops gave results similar to those obtained with atropine sulphate 1% drops both for mydriasis and for cycloplegia

The same dilatation of the pupil as is seen with atropine was obtained in all of the fifteen cases tried Mydriasis set in within $^1/_2$–$1^1/_2$ hours, and the effect persisted for 4–6 days

In four patients with refractive errors between −1 0 D and +4 0 D retinoscopy was done 2 hours after instillation of penthienate bromide This tallied with the retinoscopy findings obtained in two cases after the use of cyclopentolate hydrochloride ('Cyclogyl') and in the two others after hyoscine hydrochloride $^1/_{20}$% Since the full cycloplegia seen with atropine is also seen with hyoscine (Sorsby et al 1955) and probably also with cyclopentolate hydrochloride, penthienate bromide is adequate as a cycloplegic Further support for this finding is given by the changes observed in the curvature of the anterior surface of the lens in one case Whereas hyoscine hydrochloride $^1/_{20}$% gave full cycloplegia at 1 hour and had worn off by 28 hours, the effect of penthienate bromide, though coming on as quickly, showed no tendency to decline till after 50 hours

Penthienate bromide in a concentration of less than 2% was unsatisfactory, used as 1% drops it proved inadequate in seven of eight patients (two children and six adults), the pupil showed only partial dilatation and that after 3–6 hours

Penthienate bromide as a subconjunctival injection used in 12 patients showed efficacy of the same order as atropine used subconjunctivally in the form of 'Mydricaine' (5 minims of water containing atropine sulphate gr $^1/_{60}$ or $^1/_{40}$ and cocaine hydrochloride gr $^1/_{10}$ or $^1/_8$ to which is added 3 minims of adrenaline 1 1000) Full and persistent dilatation of the pupil was obtained with 2 mg in 0 5 ml of water and 3 minims of adrenaline 1 1000

Penthienate Bromide as Substitute for Atropine in Treatment

Penthienate bromide as 2% drops was used in patients requiring atropine for treatment

Iritis—Eleven patients with iritis, including three with hypopyon iritis, were treated with 2% penthienate bromide Three of these had originally had a subcon-

TABLE I—EFFICACY OF SOME SYNTHETIC ANTISPASMODIC AGENTS USED AS MYDRIATICS IN RABBITS

Drug *	Dose			Mydriatic effect			Remarks
	Oral (mg)	Maximal concentration permissible (%)	Maximal concentration tolerated as drops (%)	Degree	Reached within (hr)	Persistent for	
4075			1	$^3/_4$	1	48 hr	Used at maximal solubility

	Drops 1 %	8	3–6	1/2–3/4	Partial	1–3

* One other patient had a subconjunctival injection without adrenaline added There was no congestion or other reaction, and the cycloplegic effect was satisfactory

junctival injection of mydricaine, and the treatment was continued with penthienate bromide drops Four patients had penthienate bromide 2 mg subconjunctivally followed by penthienate drops Four patients were treated with penthienate bromide drops exclusively All these cases were severe, and the best results were obtained by the combined treatment of subconjunctival injection and drops

After treatment in corneal grafting—Four patients known to be sensitive to atropine were treated postoperatively with penthienate bromide drops, which were well tolerated

Other postoperative treatment—Penthienate bromide was used as the routine mydriatic in the postoperative treatment of cataract extraction in six patients known to be sensitive to atropine Recovery was uneventful

Inflammation other than iritis—Penthienate bromide was used successfully in eight cases of keratitis or uveitis

Sensitivity to atropine—In addition to these twenty nine patients, of whom ten were treated with penthienate bromide because of their known sensitivity to atropine, eight other patients with chronic uveitis or keratitis and sensitivity to atropine were treated with penthienate bromide All eighteen patients tolerated penthienate bromide well, several of them for some months, and one for 7 months now

Side effects

Dryness of the mouth after subconjunctival injection was the only untoward symptom observed

Discussion

The value of atropine as a mydriatic is attested by the fact that it has been in use for about a hundred and fifty years Its one serious defect is its tendency to produce local irritation When this happens, it is likely that any other alkaloid will also produce irritation Lachesine ('E 3') has been used widely in recent years but it proved a poor mydriatic and is in any case no longer readily obtainable More recently cyclopentolate has been used successfully, but it is also not readily obtainable, moreover its action is rapidly transient A mydriatic with properties and persistence not unlike those of atropine would therefore be of considerable importance, especially if it were safe and free from irritative effects Such an agent is apparently available in penthienate bromide

Penthienate bromide is a quaternary ammonium compound and is chemically related to the tropine alkaloids It is used clinically in the management of peptic ulcer, gastro intestinal spasm, and allied conditions, for which the dose is 5 mg by mouth three or four times a day, or the same dose by intramuscular injection in severe cases It is reputed to have minimal side effects and apparently does not produce disturbances in accommodation when given by mouth For ophthalmic use the instillation of drops or ointment and subconjunctival injection would therefore be safe if they did not exceed the stated dose of 5 mg Two drops of 2% solution instilled into each eye contain about 5 mg , such doses are consistently free from local irritative effects and can safely be repeated 4 hourly

These doses for local use can probably be safely exceeded, for much of the agent in drops is washed out from the conjunctival sac This is suggested by the experience with atropine in daily clinical use The highest systemic dose of atropine is gr 1/60, the *amount of atropine instilled into the* conjunctival sac when two drops of 1% atropine solution are used in each eye is gr 1/25 It is perhaps for this reason that atropine ointment in the same concentration is more likely to produce toxic effects, for less of the ointment is washed out from the conjunctival sac (and possibly more atropine is instilled to begin with) Similar observations apply to almost all the drops of alkaloids used in ophthalmology

It also seems that, even when administered subconjunctivally, the systemic dose is often exceeded, because one strength of mydricaine contains gr 1/40 of atropine—a concentration higher than the systemic dose

For the present, drops of penthienate bromide should not exceed a concentration of 2%, and subconjunctival injections should contain not more than 2 mg per injection to allow for the cases in which injections in both eyes are required Where only one eye requires a subconjunctival injection 4 mg would be permissible and possibly advantageous Likewise the safe dose would not be exceeded with oxyphenonium bromide in 5% solution as recommended by Fraser (1956) if the drops were used in one eye only

Penthienate bromide, possessing in safe doses the efficacy and persistence of atropine as a mydriatic, is therefore an adequate substitute for atropine in the treatment of iritis and other inflammations of the eye Whether it will prove to be entirely devoid of irritative effects is not yet known

Summary

Eight synthetic compounds with an atropine like effect were studied experimentally to establish whether they could be used as substitutes *for atropine in ophthalmology*

In greatest possible or greatest tolerated doses four agents—adiphenine hydrochloride, propantheline bromide, and experimental substances no 4075 and no 2515—proved poor mydriatics in experiments on rabbits

Of the remaining four agents which gave promising results experimentally—tricyclamol, scopolamine butyl bromide, oxyphenonium bromide, and penthienate bromide—the dosage used was limited by the toxicity of the drug in all but tricyclamol, which itself was limited by poor local tolerance

In clinical trials on 50 patients the only agent which gave adequate and persistent mydriasis was penthienate bromide

In 18 cases of sensitivity to atropine and *19 cases* of different inflammations of the eye penthienate bromide, as drops or as subconjunctival injections, was as effective as atropine and mydricaine As drops it was used in a concentration of 2%—the greatest permissible *on* systemic dosage As subconjunctival injections it was given in doses of 2 mg in 0 5 ml of water with 3 minims of adrenaline 1 1000 added

It seems likely that penthienate bromide is as adequate as atropine as a mydriatic and is probably devoid of any tendency to produce irritation

We are obliged to Dr A K Pittman, of Messrs Ciba Ltd *for so readily* supplying some of the agents used, Messrs

Bayer Ltd for supplies of penthienate bromide ('Monodral') and Messrs Burroughs Wellcome & Co and Messrs Pfizer Ltd for other substances, and Mr L J Yarrell, chief pharmacist, and Mr G J Stephens and Mr R Harding, of the laboratory, of the Royal Eye Hospital

LESIONS OF THE KIDNEY IN ACUTE RENAL FAILURE FOLLOWING SHOCK*

C Brun
M D Copenhagen

O Munck
M.D Copenhagen

From 3rd Department and Central Clinical Laboratory, Kommunehospitalet, Copenhagen

The histological findings in "shock-kidney" have been described in great detail by Bywaters and Dible (1942), Lucké (1946), and Mallory (1947) The results obtained by the microdissection technique of Oliver et al (1951) added important facts to our knowledge of the renal lesions in acute renal failure Biopsy studies have been made by Brun (1954) and Gormsen et al (1955)

In the present investigation we tried to assess the relative frequency and significance of the different structural lesions and to determine at what stage in the course of the renal failure it was possible to recognise the various histological abnormalities

Material

We investigated 33 patients with acute renal failure following shock from different causes (table I) All had severe renal insufficiency Twenty biopsies were done on 17 patients between the second and sixty sixth days after the onset of anuria In the remaining 16 cases histological preparations were made from necropsy material In 3 cases both biopsy and necropsy specimens were examined

TABLE I—CLINICAL ÆTIOLOGY OF SHOCK

—	No of patients	Survived	Died
Acute barbiturate poisoning	9	4	5
Acute peritonitis	4	0	4
Crush injury	3	0	3
Surgical complications	3	0	3
Sepsis	3	1	2
Acute pancreatitis	2	1	1
Abortion	2	1	1
Transfusion accident	1	0	1
Obstetrical complication	1	0	1
Burns	1	0	1
Traumatic cerebral œdema	1	0	1
Concealed hæmorrhage and dehydration	1	1	0
Acute gastro enteritis	1	1	0
Intoxication with carbon monoxide	1	0	1
Total	33	9	24

Methods

The kidney biopsies were done by the technique described by Iversen and Brun (1951) modified according to Kark and Muehrcke (1954) The tissue was immediately fixed in 93% alcohol Some biopsy specimens were fixed both in alcohol and in formalin, no difference in the quality of the preparations was found

The necropsy material was fixed shortly after death by injecting about 400 ml of a 4% formaldehyde solution near one of the kidneys to prevent autolysis and thus retain the histological structure of the renal tissue

In the present report we make no distinction between renal tissue obtained by biopsy and that from early fixed necropsy specimens

---

The patients are listed according to the day of histological examination Dil, dilatation of tubular lumen Flat flattening of tubular epithelium +++ lesion found throughout specimen ++ common finding +, occasional finding –, not found ?, too little tissue
* treated by hæmodialysis

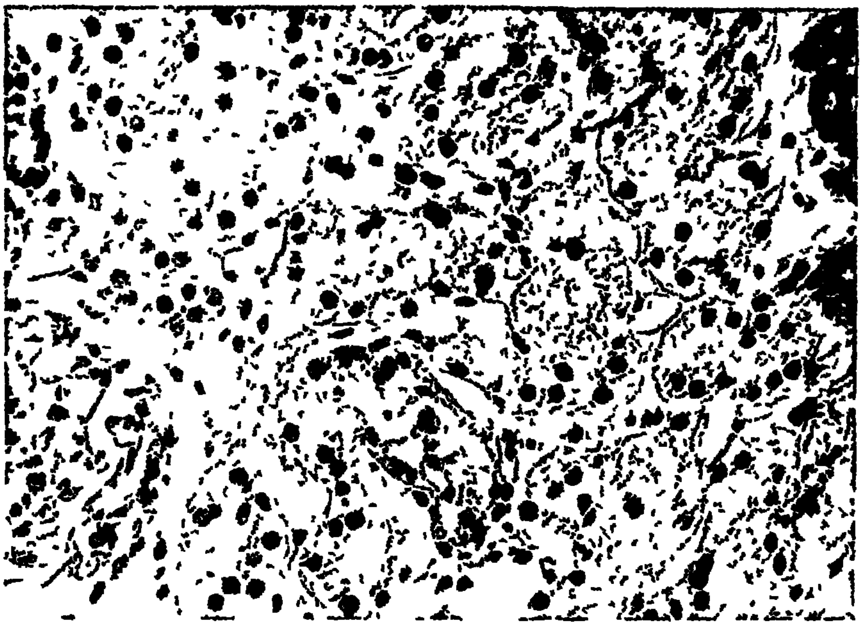

Fig 1—Case 14 kidney biopsy on seventh day of anuria from patient with severe shock and intravascular hæmolysis, showing normal proximal tubules and part of normal glomerulus, in a distal lumen a granular hæm cast and slight flattening of the epithelium, no dilatation (×280)

The duration of renal insufficiency has been taken as the number of days in which the twenty-four-hour endogenous creatinine clearance was less than 5 ml a minute

Results

The results are given in detail in table II The most striking feature was the moderate structural changes contrasting sharply with the complete functional breakdown In many patients only very slight histological abnormalities were found—e g, in case 14 the only pathological finding was a few granular hæm casts in the distal tubules (fig 1)

No acute changes were ever found in the glomerular tufts In the capsular spaces amorphous masses were discovered in many specimens, a finding which can hardly be considered of any great importance

The predominant histological changes, in order of importance were as follows

(1) *Dilatation and Flattening of Epithelium of Distal Convoluted Tubules*—The dilatation was in 3 cases very pronounced, transforming the tissue into a network (fig 2) In 12 cases the dilatation was pronounced but to a somewhat slighter degree Absence of dilatation was noted in only 6 cases In 2 of these a previous or a subsequent examination disclosed dilatation. In another of the 6 cases the examination was made after the restoration of renal function The 3 remaining cases were all examined on the third day of anuria In one of these another biopsy was done on the twelfth day with same result Thus dilatation of the distal tubules was present in nearly all the cases throughout the course of the disease, because it was observed as early as the second day and as late as the fortieth day after the onset of anuria The distal tubular dilatation was accompanied by a corresponding flat

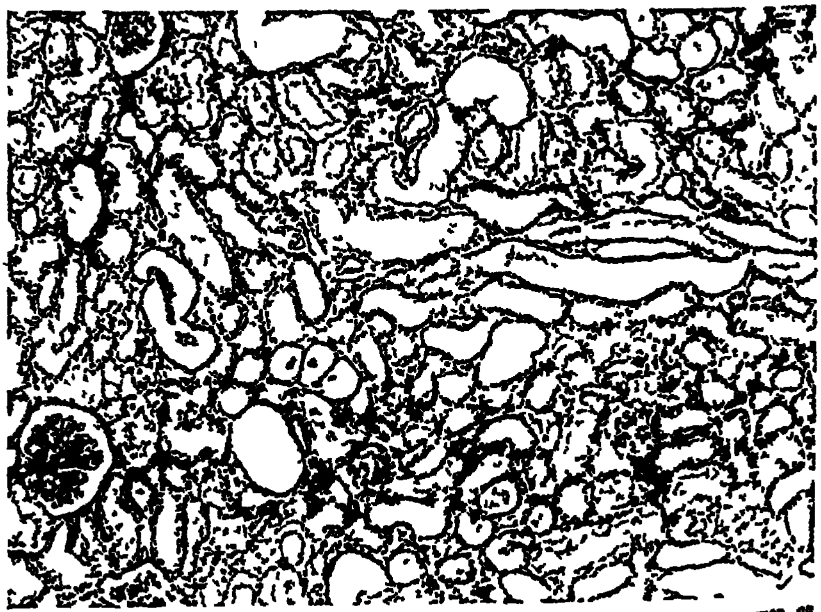

Fig 2—Case 25 necropsy specimen on twelfth day of anuria following operation for perforated gastric ulcer, showing pronounced dilatation of distal tubules with flattening of epithelium and casts in some distal lumina and well marked *hydropic* transformation of proximal tubules (×70)

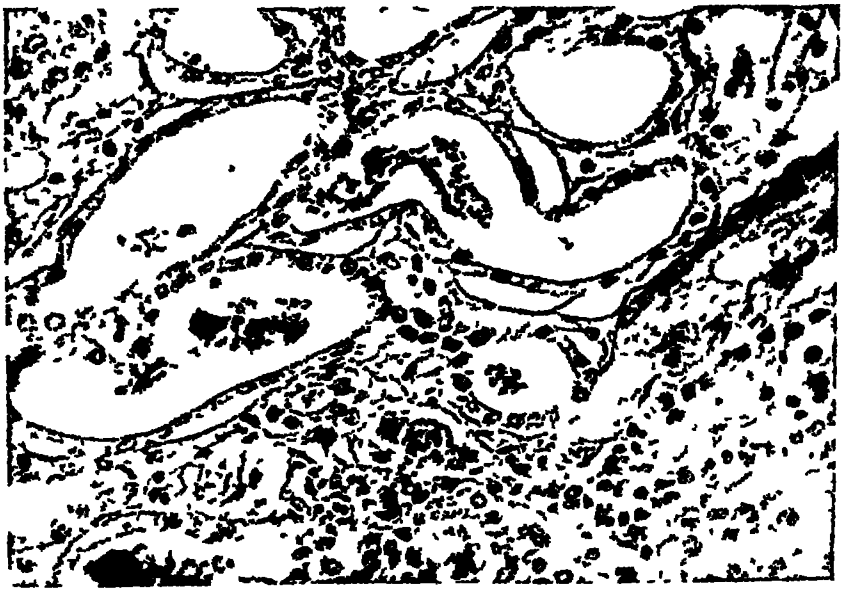

Fig 3—Case 14 necropsy specimen on fortieth day of anuria, showing dilatation of distal tubules with flattening of protoplasm and nuclei of epithelium several granular hæm casts and interstitial inflammation and œdema (×280)

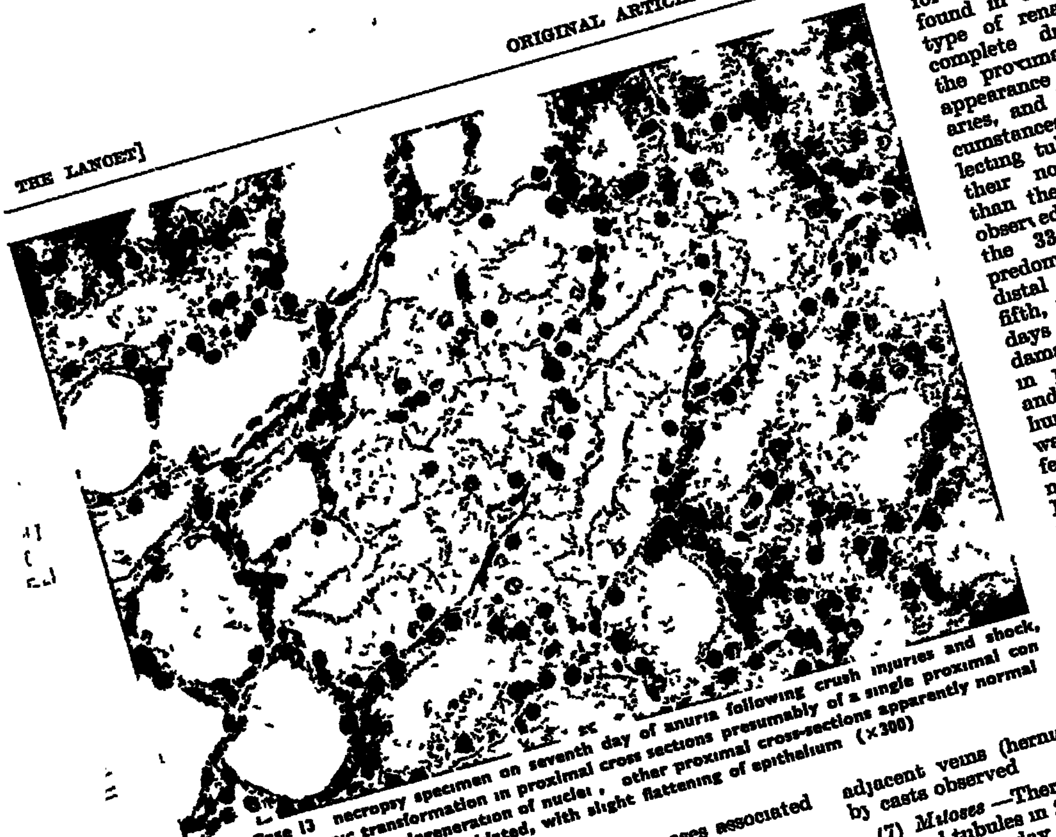

Fig 4—Case 13 necropsy specimen on seventh day of anuria following crush injuries and shock, showing hydropic transformation in proximal cross sections presumably of a single proximal convolution no obvious degeneration of nuclei, other proximal cross-sections apparently normal and distal tubules somewhat dilated, with slight flattening of epithelium (×300)

tening of the epithelium This was in most cases associated with a similar flattening of the nuclei (fig 3)

(2) *Casts* were found in all the kidneys but one In nearly all the cases the casts consisted of a granular and brownish or reddish material located in the lower nephron In some kidneys casts consisting of uniform, weakly eosinophil, hyaline material were seen, together with the type already described

(3) *Dilatation and Flattening of Epithelium in Proximal Convoluted Tubules*—In a few cases there was some dilatation of the proximal tubules, but to a much smaller extent than in the distal tubules Some flattening of the epithelium was present in about half the cases, but this change was unquestionable in only 4 patients The assessment of these slight abnormalities is rendered difficult by the fact that even normally functioning proximal tubules vary somewhat in diameter and height of epithelium

(4) *Hydropic Changes of Epithelial Cells of Proximal Tubules*—This abnormality was found in the proximal tubules, being present in about two thirds of the cases In the hydropically transformed cells the protoplasm appeared light and swollen, as if the protoplasm were œdematous The nuclei of these cells appeared normal (fig 4) Only a few nuclei were present in some cross sections, but this is not surprising when the swollen appearance of the cells is taken into account In 3 cases the hydropic changes were present in all the cross sections of the proximal tubules, in the remaining cases there were groups of affected cross sections throughout the specimen

(5) *Infiltration and Œdema of Interstitial Tissue*—Small scattered foci consisting of lymphocytes histiocytes plasma cells and occasional leucocytes were found in 12 cases in 8 of which moderate interstitial œdema was present

(6) *Tubular Necrosis*—Special attention was paid to tubular necrosis, which is generally accepted as the typical structural change in this disease Nothing like the frank necrosis seen in cases of renal cortical necrosis or the change observed in the kidney after the renal artery has been clamped for two or more hours, was found in our material In this type of renal damage there is complete disintegration of all the proximal tubules, with disappearance of nuclei, cell boundaries, and lumen In these circumstances the distal and collecting tubules seem to conserve their normal structure better than the proximal (fig 5) We observed tubular necrosis in 5 of the 33 patients The lesion, predominantly situated in the distal tubule was found on the fifth, ninth, twelfth, and fortieth days of the disease The tubular damage, when present, consisted in poor staining of the nuclei and desquamation of the epithelium When this type of damage was found it was only in very few cross sections, located between normal looking tubules (fig 6) In some preparations focal inflammation was found close to the tubules in cross sections, but, owing to the dense cellular infiltration it was impossible to decide whether or not disruptive tubular lesions were present (fig 7) Unquestionable tubular rupture was not observed In no case was bulging of tubules into adjacent veins (herniation) or penetration of venous walls by casts observed

(7) *Mitoses*—There were mitoses in the epithelium of the proximal tubules in 2 cases and in that of the distal tubules in 5 cases The day of examination in these patients varied from the third to the twenty second after the onset of anuria

Table II shows that the histological changes occurred with very nearly the same frequency in both the early days of the disease and the later stages There was a noteworthy change in only 1 of the 6 cases where the examination was repeated In case 14 the pronounced dilatation of the distal convoluted tubules present on the seventh day was absent on the fortieth day

The lesions in most cases were characteristically focal

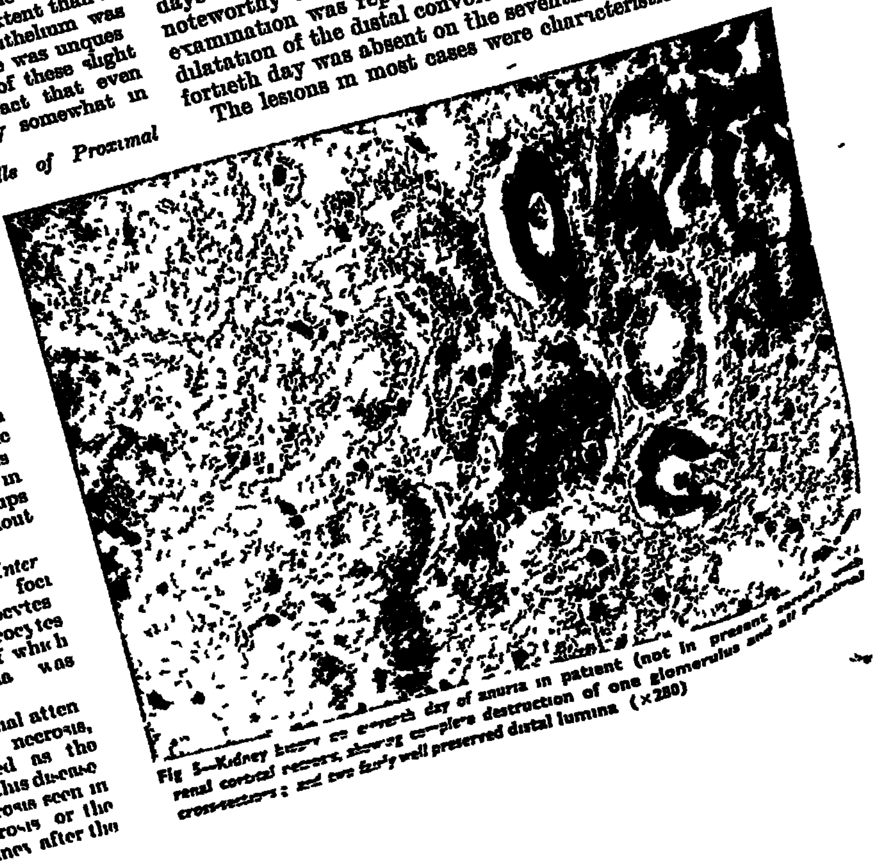

Fig 5—Kidney biopsy on seventh day of anuria in patient (not in present series) with renal cortical necrosis, showing complete destruction of one glomerulus and all proximal cross-sections; and two fairly well preserved distal lumina (×280)

in distribution, small affected areas being found here and there In a few preparations all, or nearly all, the cross sections were involved No correlation was observed between the severity of the disease and the grade of histological abnormality

Discussion

The structural changes hardly differed from those described by other workers The most characteristic alteration was dilatation and flattening of the epithelium in the distal convoluted tubules, being present in nearly all the cases This is in close accordance with the description given by Lucke (1946)

The presence of pigmented casts in the lower portion of the nephron was another characteristic feature The casts varied from brownish granular conglomerates to reddish corpuscles which were hardly distinguishable from erythrocytes, a finding which correlates well with the almost constant presence of hæmaturia It is remarkable that no casts were found in the proximal tubules

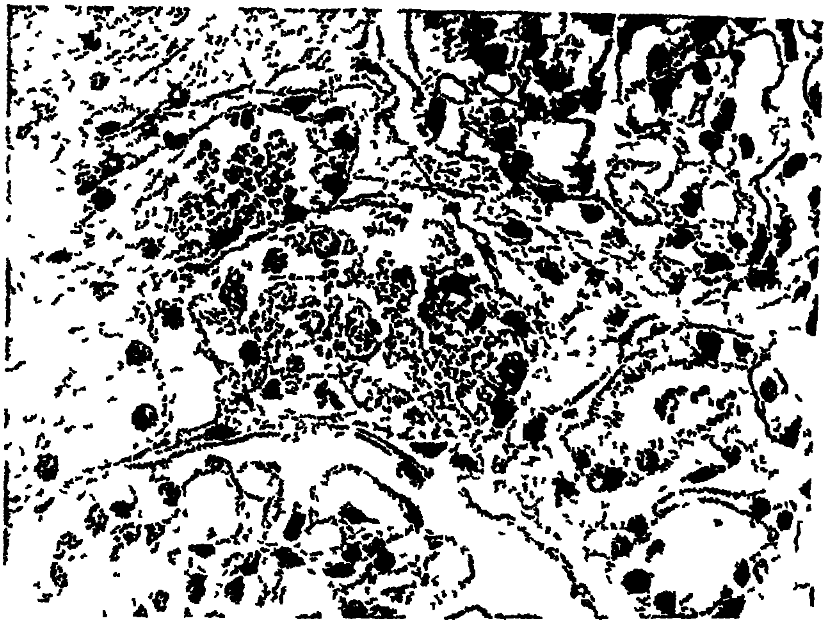

Fig 6—Case 7 biopsy on fifth day of anuria following traumatic cerebral œdema with shock, showing normal glomeruli and hydropic transformation in proximal cross-sections, two distal convoluted tubules with poorly stained nuclei desquamation of epithelium and two adjoining distal cross sections fairly well preserved (×500)

Necrosis of tubular epithelium was uncommon, when it was present, only a very few isolated cross sections were involved Admittedly the traditional two dimensional histological technique is a poor tool in the search for the tubulorrhexic lesion described by Dunn et al (1941) and Oliver et al (1951), but, even using the microdissection technique, Oliver et al reported that "in severely damaged kidneys, not all nephrons are affected, and in the moderate example only occasional ones"

Necrosis of tubular epithelium cannot be distinguished from the post mortem autolytic changes which are universally present if fixation or necropsy is not done immediately after death

Hydropic transformation of the protoplasm of the epithelium in the proximal tubules was common and striking in a large proportion of cases Many different substances can produce these hydropic changes—e g, hypertonic solutions of sucrose, glucose, lactose, and sodium sulphate (Lamy et al 1906) Helmholz (1933) and Allen (1951) observed similar changes after the injection of other substances—e g, urea, xylose, inulin, acacia, and creatinine Dextran and similar plasma substitutes can also produce this lesion in laboratory animals (Goldenberg et al 1947, Bing et al 1951) and in patients with or without acute renal failure (Johnston et al 1953, Vickery 1956) Using a specific staining method Vickery (1956) showed that the hydropic changes were correlated with intracellular dextran in the histochemical preparations

Milne (1955) and Relman and Schwartz (1956) suggest that the hydropic changes can be produced by severe potassium deficiency, but the responsibility of dextran and of inulin could not be excluded in their patients

In the present material from patients with acute renal failure there was a high correlation between the presence of hydropic changes and the infusion of the above mentioned substances, 21 of the 24 patients with hydropic changes having received infusions of dextran, sucrose, or sulphate Similar infusions had been given in only 1 of the 10 patients in whom no hydropic changes were found There was no correlation between the serum potassium level and the existence of hydropic changes

Although we cannot explain why no hydropic changes were found in 1 patient who had received dextran our results suggest that hydropic changes in the proximal tubules are not typical for acute renal failure as such but are the result of therapeutic measures

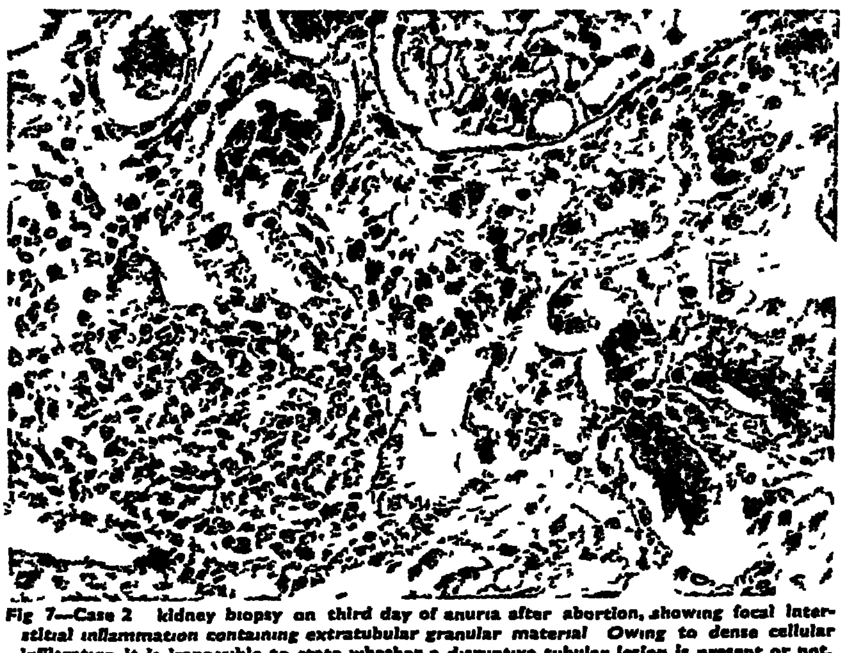

Fig 7—Case 2 kidney biopsy on third day of anuria after abortion, showing focal interstitial inflammation containing extratubular granular material Owing to dense cellular infiltration it is impossible to state whether a disruptive tubular lesion is present or not. Distal cross-sections containing hæm casts or cellular debris are seen Proximal convolutions and glomeruli normal (×280)

Summary and Conclusion

In kidneys from 33 severe cases of acute renal failure following shock the most important histological changes were (1) dilatation of the distal convoluted tubules with attendant flattening of the epithelium, (2) pigmented casts in the distal convoluted tubules, Henle's loops, and collecting tubules, and (3) interstitial changes consisting of small foci of cellular infiltrations and œdema

In many cases there were some dilatation of the proximal tubules and moderate flattening of the epithelium but rarely more than can be seen in normally functioning tubules

Hydropic changes in the epithelium of the proximal tubules were a common finding, but it is highly probable that this change was due to infusions of dextran, sucrose, or sulphate, and not to the kidney disease as such

Tubular necrosis and mitoses in the tubular epithelium were found in a few specimens No unquestionable tubular disruptive lesions were seen, but the ordinary histological technique is insufficient to show this

The various histological changes occurred nearly with the same frequency in both the early days of the disease and the later stages

The most impressive general observation was the contrast between the moderate structural changes and the complete functional breakdown

INSULIN TREATMENT OF SCHIZOPHRENIA

A CONTROLLED STUDY

BRIAN ACKNER

INSULIN coma therapy of schizophrenia was introduced by Sakel over twenty years ago (Sakel 1935), and a vast literature on the results of this treatment has since accumulated And yet, despite these numerous studies, despite the claims of enthusiastic supporters, and despite the vigorous protestations of Sakel himself (Sakel 1950), the evidence for the value of insulin remains far from convincing In recent years papers critical of the evidence for the value of insulin have been published (Bourne 1953, David 1954 Gottlieb and Huston 1951, Lifschutz 1954), and there is now a growing tendency to try the effect of the new "tranquillisers" before resorting to insulin therapy Boardman et al (1956) claim similar results for treatment with chlorpromazine, and even previously enthusiastic exponents of insulin therapy have reported that they have almost given up the treatment (J N P Moore, personal communication)

If insulin coma is effective, the growing tendency to abandon it must be reversed If it is not, patients are being exposed to risks, and the hospital service is incurring expense to no good purpose If it is true that insulin coma has a specific influence on schizophrenia more research should be concentrated on the physiological mechanisms involved If there is no such specific influence, further inquiry along these lines is a waste of time and money

Clearly a reassessment of the results of insulin therapy is urgently needed, and the present work is an attempt to supply this need by means of a study designed to avoid some of the fallacies present in previous work Since the need for a further assessment arises from these fallacies, they will now be considered in some detail

Fallacies in Previous Studies

Selection of Patients

To compare the reported results of treatment by different workers, it must be possible to assess how comparable are the various schizophrenic populations, yet the age distribution and the proportion of schizophrenic subtypes composing the group studied are often not given Some workers have included atypical or schizo affective cases but have not indicated their proportion in the total group, although they are well known to have a more favourable outcome (Harris and Lubin 1952, Harris and Norris 1955)

The duration of illness is now accepted as one of the most important prognostic factors in schizophrenia, yet many studies have been rendered inconclusive by the failure to separate the recent from the chronic cases and to specify results in relation to the duration of the psychosis

Reports on large groups of schizophrenics from different hospitals involve differences in the type of patient admitted, dissimilar diagnostic practices, variability in intensity of treatment, and lack of consistency in assessing outcome

There is evidence that, in recent years, mental-hospital admissions have contained a higher proportion of less severely ill patients with a more favourable prognosis (Harris and Norris 1954) As a result the outcome of even the illnesses of recent onset treated with insulin cannot validly be compared with those of the pre-insulin era The finding by Malzberg (1943) that, in New York State, both the admission rate and the discharge-rate of schizophrenics had risen since the institution of insulin therapy suggests that belief in the efficacy of the treatment, given as early as possible in the illness, and fear of depriving the patient of its benefits had led to an increased admission of early or doubtful cases

An adequate assessment of the results of insulin coma therapy necessitates the comparison of the outcome of treated cases with those who have not received insulin but in all other respects can be considered to be alike Many workers have not reported control series at all, or have referred to those of workers from other hospitals, but all the large control series reported are derived from the pre insulin era Though details are commonly given for the composition of the insulin-treated groups, less attention is often paid to the controls, and criteria of selection are often not indicated

Even if properly matched untreated cases from another hospital or from the same hospital but derived from an earlier era, cannot properly be regarded as comparable Apart from the factor of changing patterns of admission mentioned above, the influence of modifications in the hospital environment, changes of doctors and nurses, and altered attitudes towards hospital care cannot be ignored A remission in the absence of specific treatment does not necessarily indicate that it is "spontaneous" and that no other favourable influences have played a part In the past the untreated cases were often a neglected group, but in recent years the increasing emphasis on resocialisation and individual and group approaches has so altered the pattern of hospital care that many factors unrelated to the physical treatment are brought to bear on schizophrenics in a manner that rarely existed previously The belief in the greater possibility of recovery, the atmosphere of therapeutic enthusiasm, and the increased medical and nursing attention must all be powerful forces promoting recovery

This view is supported by the recent work of Hoenig et al (1956), who compared the outcome of a group of early schizophrenics in the Maudsley Hospital in 1934–35 with a comparable group in the same hospital in 1948–50 They found that the results in the later group were much better than those in the earlier group, who had received no physical treatment However, the results in those cases of the later group who had received no physical treatment were also much better than those of the earlier group, and it was concluded that factors other than physical treatment must be concerned in the difference in outcome between the two groups

A few workers have tried to compare an insulin-treated group of patients with a parallel control group cared for under similar conditions at the same time, but none of the studies is satisfactory

Notkin et al (1939) compared a group of insulin treated schizophrenics with a control group of patients in the same ward receiving saline injections, and they claimed no difference in outcome between the two groups However, no criteria of selection for the two groups were given, and the patients appeared to be largely a chronic group not matched for duration of symptoms The method of clinical assessment and follow up procedure was also unsatisfactory

Lipschutz et al (1939) compared groups of chronic schizophrenics treated with (1) insulin coma and resocialisation, (2) insulin coma without resocialisation, and (3) physiological saline solution and resocialisation They claimed superiority of results in that order However, the groups were small, and no criteria of selection were stated The insulin and resocialisation group which had the best outcome was a larger group than the others and appeared to contain more cases of shorter duration

Libertson (1941) compared an insulin treated group with an equal number of patients not receiving insulin and claimed no difference in outcome between the groups for the early cases However, the controls were cases unsuitable for insulin because they were either chronic or already recovering Thus, although the average duration of symptoms of the controls was much larger than that of the schizophrenics, the short duration cases in the control group appeared to consist largely of specially selected cases

Gottlieb and Huston (1951) treated three groups of schizophrenics with insulin, brief psychotherapy, and electroconvulsions and claimed that the outcome was not significantly different in the three groups However, no criteria of selection of cases were given, the duration of symptoms for each group was not stated, and the group appeared to differ in their composition of subtypes Furthermore, their technique of insulin coma therapy is open to criticism

Lifschutz (1954) compared an Army group of insulin treated and non treated schizophrenics and claimed no difference in outcome between the two groups However, no criteria for selection were given, and, although these groups were named acute, chronic, and unknown, there was no indication that they were strictly matched for duration of symptoms Electroconvulsions were apparently given to both groups, but to what extent was not stated

Nowhere does there appear to have been reported a control group properly matched for age, sex, subtypes, and duration of symptoms, selected by randomisation, and treated at the same time and under general conditions similar to an insulin treated group

Technique of Insulin coma Therapy

A lack of consistency in insulin-coma technique often makes comparison of results reported by various workers difficult Often no details of the technique are reported at all, and in some investigations reported there may be variability between different workers in their criteria of sopor and coma, in the duration of coma permitted, and in the number of coma treatments given

Another serious difficulty arises from the almost general practice of administering electroconvulsions (or leptazol in previous years) in a variable manner during the course of insulin administration Clearly any control group which has not also received electroconvulsions cannot be regarded as valid for the assessment of the effect of insulin complicated in this way

Weinberg and Goldstein (1942) treated 100 schizophrenics with insulin coma three months after their failure to respond to metrazol therapy, and they claimed a high remission rate However, since a comparable group of insulin failures subsequently treated with leptazol was not reported, the factor of increased duration of hospital treatment could not have been taken into account

Rees (1949) compared the results of treatment with insulin electroconvulsions, and electronarcosis in 160 schizophrenics and claimed definite superiority for insulin treatment However, although the three groups were well matched, there is no indication whether the 160 patients were consecutive admissions or drawn from a large population, and how the selection was made which determined the treatment

Mode of Assessment of Outcome

In any controlled clinical trial the potential bias of the observer must be excluded by his having no prior knowledge of the treatment given to the groups being assessed Unfortunately this condition has never been achieved in the reported studies on insulin treatment Not only have the results always been assessed with a full knowledge of which were the controls and which were the insulin treated patients but also commonly the assessment was made by those responsible for the therapy and therefore not disinterested observers

The variable and often ill defined criteria of outcome of treatment used by many workers has created difficulties in the assessment of results

Sometimes only immediate outcome of treatment has been considered, and often results have been expressed solely in terms of percentage of patients discharged or allowed out on parole

The length of time following treatment at which the patient leaves hospital is often not stated, and in these circumstances the success cannot necessarily be ascribed to the treatment

Assessment in terms of reduced hospitalisation time also cannot be accepted by itself as a valid criterion, for increasing pressure on beds in overcrowded hospitals, and the tendency for the enthusiastic therapist to discharge his treated patients earlier than was the custom, will both tend to affect discharge policy in the direction of reduced stay in hospital

Furthermore, the ability of a patient to leave hospital and to remain in the community must clearly depend in part on social factors, such as the home conditions and the capacity of relations to tolerate and adjust to psychotic symptoms and behaviour abnormalities

In reporting results the categories "recovered" and "much improved" are often grouped together in different ways by various workers

Some workers believe that no case of schizophrenia severe enough to be institutionalised recovers without some personality deterioration (Lewis and Blanchard 1931)

Ross and Malzberg (1939) report high recovery and much improved rates, claiming "recovery" to mean symptom free with insight, and "much improved" to mean symptom free without insight

Most other workers have placed less emphasis on the presence of insight and have been prepared to accept as "recovered" all symptom free cases while including under "much improved" or "social recoveries" those patients still showing mild symptoms or personality defects who are able to return to an independent existence in the community

The frequent grouping together of these two categories allows of much variability in the range of outcome but nevertheless is to be preferred to the use by some workers of the category "remission" often without any attempt at all to define terms.

Follow-up Studies

Many follow-up studies have not indicated the methods used to assess the clinical status of the patient:

Contacts with the patient or with a relation by post, or by interview with the doctor or a psychiatric social worker, have all been used, but in what proportions in any one study it is often difficult to determine.

Sometimes the follow-up periods are fixed from the time of discharge of the patient from hospital instead of from the time of termination of treatment; consequently recoveries which have occurred in hospital long after the termination of treatment are ascribed to the treatment.

The same source of possible error occurs in the common practice of reporting the clinical status at each follow-up period in terms of percentages of the original group instead of in terms of the previous follow-up group. By this procedure recoveries occurring many years after the termination of treatment are ascribed to the treatment.

Sometimes no fixed follow-up periods are stated, and results are given for a group within which the follow-up duration varies from a few months to a few years.

Sometimes relapse rates are really readmission rates, and no account is taken of the relapsed cases remaining in the community.

In reporting follow-up results little account may be taken of untraced cases or the results stated in terms of the percentage of cases actually followed up.

Design of Controlled Study

The design of a controlled study of the therapy of schizophrenia is evidently difficult because of the ill-defined diagnostic criteria, the heterogeneous nature of the disease, its variable and only partially predictable spontaneous course, and the lack of clear-cut standards of improvement or of recovery. To assess effectively the results of insulin coma therapy many criteria must be satisfied, and among them the following appear important:

The patients selected should all have undoubted schizophrenia and be such that all experienced psychiatrists would regard them as good subjects for the treatment. The patients should thus all have a clearly defined onset of symptoms of under one year's duration and should not have had an insidious onset or a marked abnormal personality.

The age range should be such as to exclude the menopausal and adolescent psychoses, which may have a different prognosis.

To avoid including those with a tendency to rapid remission, patients should not be accepted until a few weeks after their admission.

Those undertaking the insulin therapy should not be responsible for the selection, diagnosis, and subsequent assessment of the patients.

The schizophrenic group so selected should be divided into diagnostic subtypes because these are usually believed to differ in their outcome, and the subtypes should be separately randomised into treatment and control groups. Both these groups should be treated contemporaneously under the care of the same doctors and nurses. They should be treated in the same ward; and, except for the actual administration of insulin, the controls should receive treatment which in all other respects is comparable to that given to the insulin group.

Those originally responsible for selecting the patients should assess results without any knowledge of the treatment received by the patients. This assessment should be made in accordance with previously agreed and defined criteria, and it should be made at suitable intervals after the end of treatment.

Present Investigation

Ackner (1951) suggested a project fulfilling the above criteria in which it was proposed that the controls should receive barbiturates instead of insulin to induce loss of consciousness. The implementation of this proposal took time but was finally achieved in a coöperative study initially on patients in Cane Hill Hospital and later including also patients in the Maudsley and Bethlem Royal Hospitals.

One of us undertook the insulin treatment of the Cane Hill Hospital patients, while another was responsible for the treatment of the Maudsley and Bethlem patients. The patients treated had been originally admitted under either our own care or the care of other physicians at the hospitals who had previously agreed to their patients being included in the project.

Patients with a presumptive diagnosis of schizophrenia, aged 18–40, with no history of previous psychotic symptoms, and with an apparent history of less than a year's duration were seen after they had already been fully investigated for some weeks in hospital. They were diagnosed and selected by the two of us not responsible for the treatment at the hospital in question, and no patient was accepted unless there was complete agreement on the diagnosis and duration of symptoms. No atypical cases or those already showing signs of recovery were accepted. So strict were the criteria of selection that, of all early schizophrenics offered as being suitable, nearly 50% were rejected on the grounds of doubt about diagnosis or duration of symptoms. After a patient had been accepted and the diagnostic subtype (hebephrenic, paranoid, catatonic, schizo-affective) agreed, the randomisation into the insulin or narcosis group was made by the physician responsible for the treatment and without the knowledge of the other two concerned.

METHOD OF TREATMENT

Insulin and Control Groups

The randomisation into insulin and narcosis groups was made for each sex separately for the Bethlem-Maudsley patients and for the Cane Hill patients. The procedure was as follows:

Paranoid or hebephrenic schizophrenia.—The grouping of the 1st paranoid or hebephrenic patient of either sex was decided by the toss of a coin; the 2nd patient of the same sex and diagnostic category was allocated to the opposite group; the 3rd patient according to the toss of a coin, and so on. If a patient did not complete treatment for such reasons as discharge against advice and technical difficulties in the insulin series, he was removed from the group, and his place was taken by the next patient with the appropriate sex and subcategory.

Schizo-affective psychosis and catatonic schizophrenia.—Patients with schizo-affective psychosis and catatonic states often respond well to electroconvulsions; so, to avoid the confusion of results caused by combined treatment, these patients were first given a course of ten electroconvulsions at the frequency of 2–3 treatments a week. If they were considered then by the assessors to have recovered, no further treatment was given; but, if they were considered still to be actively schizophrenic, each patient was randomised as above into the insulin or narcosis group.

Therapeutic Environment

Every matched pair of patients having insulin or narcosis treatment was treated, so far as practicable, in the same therapeutic environment in all other respects. The fact that two separate insulin units, at Bethlem and at Cane Hill, were used, and that the sexes were segregated for treatment, did not impair this aim, because all male and female patients accepted into the series were matched separately at the two hospitals.

At Bethlem Royal Hospital the insulin unit is shared by males and females, who are segregated only for treatment, toilet, and sleeping. The unit is self-contained and only includes patients under treatment.

At Cane Hill Hospital separate insulin units for male and female patients are situated in two wards which are also occupied by patients not under insulin treatment. In both hospitals all patients having insulin treatment, whether in our series or not, spent their non-treatment hours as a group, engaging in the usual programmes of occupational and recreational therapy. All the patients in our series were told they were having coma treatment and were in no way distinguished from the patients in the unit who were not in our series The purpose of the project was explained to the nurses, who were carefully trained to treat every patient alike All the patients received the same number of injections and doses of medicine in the course of the day, whether they were having insulin or narcosis treatment

Drugs Used

The problem of a suitable narcotic agent was investigated at Cane Hill Hospital, where, after a short trial, it was decided that equal parts of sodium amylobarbitone and sodium quinalbarbitone produced within an hour a state of deep sleep which tended to lighten considerably after a further thirty minutes Subsequently the introduction of dexamphetamine solution into the stomach would awaken the patients after a further period of about fifteen minutes The following agents were then used

(1) Soluble insulin (2) Sterile water		for intramuscular injection
(3) *Narcosis control mixture*		
Infusion of gentian	$^1/_2$ drachm	to be taken by mouth
Brandy	$^1/_2$ drachm	
Azorubrum	4–5 min	
Aqua ad	$^1/_2$ fl oz	
(4) *Narcosis mixture*		
Sodium amylobarbitone	gr 3	to be taken by mouth
Sodium quinalbarbitone	gr 3	
Brandy	$^1/_2$ drachm	
Aqua ad	$^1/_2$ fl oz	

Brandy was needed to suppress the taste of the barbiturates which were difficult to match, azorubrum was needed to match the red colouring given off by the sodium quinalbarbitone tablet

Therapeutic Technique

Treatment was given daily except on Saturdays and Sundays and started at 7 A M after a fast from 7 P M on the preceding day Patients in the insulin group received the appropriate intramuscular injection of soluble insulin, and those in the narcosis group were given a similar injection of sterile water At about 8 45 A M each patient in the narcosis group was given a drink of narcosis mixture, and every insulin-group patient a similar drink of narcosis control mixture

For the insulin group the definitions of coma and sopor were those used by Sargant and Slater (1954)—i e, coma is a state of unconsciousness in which the patient does not react purposefully to painful stimuli, and sopor is a state from which the patient cannot be fully aroused although able to react purposefully to painful stimuli

For the narcosis group dosages of the narcosis mixture were gradually increased until deep sleep came on at about 9 30 A M, many of the patients later reaching a state of unconsciousness equivalent to coma

After thirty minutes' coma the insulin-group patients were given a nasal feed of one pint of 33% glucose solution, while the narcosis group patients received a nasal dose of one pint of dexamphetamine solution made by dissolving in water a dose of dexamphetamine in milligrammes equal to twice that of the combined barbiturates in grains

Any insulin group complications were treated in the standard manner It was intended that, if a barbiturate coma became "irreversible," methamphetamine should be given intravenously, but the occasion never arose

35–40 insulin comas (or the narcosis equivalent) were administered in all the cases This sometimes involved a slightly longer period of treatment for the insulin group owing to the longer time needed to obtain coma dosages of soluble insulin

ASSESSMENT OF RESULTS AND FOLLOW-UP PROCEDURE

On completion of treatment every patient was seen by the two physicians who had not been responsible for the treatment, and the mental state was assessed without any knowledge of the treatment received Six months, a year, and thereafter yearly after the end of treatment the patient was again seen by the same assessors (who were still ignorant of the treatment given) and classified on two 3-point scales, one referring to his clinical state judged at interview and the other to his present social status These scales were as follows

Clinical state

(1) Symptom free and apparently fully recovered
(2) Residual defect
(3) Psychotic symptoms still present

Social status

(1) Independent
(2) Socially dependent
(3) Hospital inmate

Patients were judged to be fully recovered when no psychotic symptoms or impairment of personality could be detected and when they had apparently returned to their prepsychotic state If any psychotic symptoms at all were detected they were so categorised If no psychotic symptoms were detected but the patient exhibited personality changes—e g, flattening of affect, loss of drive, and poor concentration—he was categorised as "residual defect" Patients were judged to be "independent" if they were working and earning a living or performing their duties as housewives normally If dependent on relations or social agencies for their keep or if inefficient as housewives, they were categorised as "socially dependent"

No attempt was made to rate patients on the much used but unsatisfactory category of "much improved" Our patients were either clearly recovered or still ill in various respects

RESULTS

The clinical state at the end of treatment had often not settled fully enough to categorise adequately, but the picture six months after treatment had ended was clear enough to enable a reliable rating to be made

Up to date some patients have been followed up for more than two years, but others have not yet completed their six-month follow-up period This report present the results of the first 25 matched pairs who have completed the first six-month follow up period Of the 50 patients 48 were personally seen by the assessors, and in many cases relations were interviewed by them at length The 2 patients not seen were both in other mental hospitals, and comprehensive reports concerning their condition were received

Of the 25 pairs 12 were female and 13 male There were 18 pairs of paranoid schizophrenics, 6 pairs of hebephrenics, and 1 pair of schizo-affective psychotics

The results are shown in the accompanying table A brief note on the schizo affective and catatonic patients accepted for the series during the period under review is needed

The 11 schizo affectives were all in a state of consistent depression but showed in addition such schizophrenic features as delusions of persecution and influence of an

RESULTS

Classification	Insulin			Controls		
	Cane Hill	Bethlem Maudsley	Total	Cane Hill	Bethlem Maudsley	Total

Out of hospital but dependent	2	3	5	2	1	3
In hospital	5	1	6	6	4	10
Dead	0	1*	1	0	0	0
Total	14	11	25	14	11	25

* Killed while cycling after discharge from hospital

odd bizarre nature, passivity feelings, or thought disorder of schizophrenic type 6 recovered completely after electroconvulsions, 2 discharged themselves against advice, and 3 went on to the insulin/narcosis series Of the 3 catatonics, 1 recovered completely after electroconvulsions, and 2 went on to the insulin/narcosis series but being of opposite sexes did not form a matched pair

Discussion

It will be readily seen from the table that the results for the insulin and narcosis groups are so similar that no statistical treatment of significance is necessary The only possible exception relates to the number of patients remaining in hospital, where the figures show an apparent tendency in favour of the insulin group However, the difference between the 10 in the narcosis group and the 6 in the insulin group remaining in hospital is statistically not significant whether considered separately for each hospital or for the total of the two together

It will be seen that the similarity in outcome for the two groups applies not only to the overall figures but also to the two hospitals considered separately This is very striking in view of the fact that the hospital environments and personnel are different and that Bethlem and the Maudsley hospitals only admit voluntary patients Furthermore the results of treatment are not only remarkably similar but are also good Six months after treatment 40% of the patients remain fully recovered (excluding any who might be considered much improved,) and this figure has not been bettered in any reported series

The results presented are based so far on a small number of patients However, many other reported series have not contained as many as 50 early schizophrenics, and our series would have been larger by now if so many cases had not been rejected at the time of selection The small size of the series is, however, probably compensated for by the careful selection and randomisation of the groups At no time have the assessors ever had any knowledge of the group to which a particular patient might belong, and they still remain in ignorance As a result no bias in assessment was possible, and rating was often severe On a few occasions a relation insisted that a patient was fully recovered and completely back to his former self, but this was not accepted and a rating of "residual defect" was made

The results so far show that there is no significant difference in the outcome of treatment whether unconsciousness has been induced by insulin or by barbiturates They do not demonstrate that the coma regime has no therapeutic effect During insulin therapy patients are subjected to powerful group influence and receive increased medical and nursing care in a special setting Daily they are exposed as a group to the threat of being rendered unconscious Daily they are brought back to consciousness by doctors and nurses on whom they become dependent The new relationships so built up cannot be ignored, for it could be that the coma régime is helping to establish that lost capacity for relationship with others But the results suggest that insulin is not the specific therapeutic agent of the coma régime as has so often been claimed We intend to follow up these and other patients for a longer period and present further results at a later date

Summary

Schizophrenics, aged 18–40, with a history of psychosis for less than a year, were randomised separately, according to sex and diagnostic subtype, into an insulin and a barbiturate group

The insulin group received the standard insulin coma therapy, and the barbiturate group was treated in the same ward, under similar conditions, the only difference in treatment being that unconsciousness was produced by oral barbiturate

The initial diagnosis and subsequent assessment of outcome were made without any knowledge of the treatment given

The results of treatment for the first 50 patients followed up at the end of six months reveal no significant differences between the two groups

No conclusion can be drawn about the therapeutic value of the coma régime, but the results suggest that insulin is not the specific therapeutic agent

We are indebted to Dr A Walk, physician superintendent, Cane Hill Hospital, for willing collaboration, Dr D L Davies, Dr J Dewsbery, Dr W Linford Rees, and Dr F Post for referring patients to us, Mr A E Maxwell, of the Institute of Psychiatry, for statistical advice, Mr J Tremowden, chief pharmacist, Cane Hill Hospital, for his help, and the nurses and junior doctors of Bethlem Royal and Cane Hill Hospitals for their conscientious supervision of the treatment

THE EFFECT OF AN AEROSOL DETERGENT IN CHRONIC BRONCHITIS

K N V PALMER
M A, M D Camb, M R C P
SENIOR LECTURER IN MEDICINE IN THE UNIVERSITY OF ABERDEEN

IN chronic bronchitis the bronchial secretion is more copious, adhesive, and viscid than normal During an acute infection it is opaque, yellow, and less viscous During recovery and in the chronic phase it becomes clear, gelatinous, and more viscous (Elmes and White 1954) When the sputum is purulent its viscosity can be reduced by streptodornase as an aerosol (Armstrong and White 1950), but when the sputum is mucoid its viscosity cannot be reduced by any specific enzyme

Since the purulent phase lasts only a few days when suitable antibiotics are used, and since patients expectorating mucoid sputum do not benefit from chemotherapy whatever organism is present (May 1953), the great problem is to reduce the viscosity and thereby to aid the expectoration of the viscid mucoid sputum during the chronic phase of bronchitis

American workers have reported that the proteolytic enzyme trypsin given as an aerosol is of value for this purpose (Unger and Unger 1953) This substance is irritant, however, and the coughing it produces is probably the most important factor in the removal of the sputum Moreover, since trypsin is a foreign protein there is a risk of sensitisation, and pre malignant changes in the bronchial mucosa have been reported after its use (Farber et al 1954)

Aerosol detergents have been developed to reduce the viscosity of the mucoid bronchial secretion and to aid expectoration (*British Medical Journal* 1954) The effect of such a preparation, 'Alevaire,' in chronic bronchitis is reported here Alevaire is produced by Bayer Products It contains 0 125% of a detergent superinone ('Triton

WR 1339 ') in a sterile aqueous solution containing 2% sodium bicarbonate and 5% glycerin The glycerin is added to stabilise the aerosol droplets Alevaire is administered in a nebuliser which delivers a fine " dry " mist with a particle size of 0 5–3 0 µ The nebuliser is attached to a suitable air compressor or oxygen supply The two atomisers which we have used for this purpose and found very suitable are the 'Collinson' and the 'Oxygenaire' Alevaire is unsuitable for use by steam inhalation

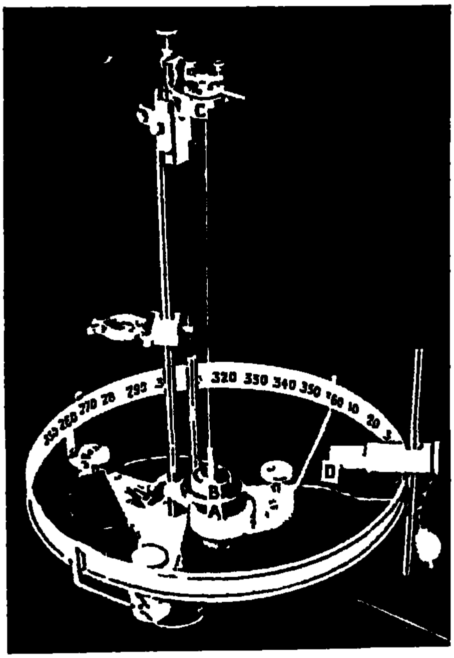
Method

Twenty-five patients with chronic bronchitis were studied They had been in hospital for several weeks, were expectorating mucoid sputum, and were not having any drugs, hence they were all considered to be in a stable phase Throughout the period of observation they were ambulant in a well heated and well-ventilated ward, and an adequate intake of fluids was ensured

The trial period extended over three consecutive weeks (1) a week with no treatment, (2) a week of daily inhalations of alevaire, and (3) a week of daily inhalations of a control solution The order of (2) and (3) was decided by random selection The nature of the substances given was unknown to the patient, the nurses, and the persons making the clinical assessment and measuring the viscosity The control solution was the same as alevaire except that it did not contain the detergent—i e, it consisted of water, 2% sodium bicarbonate, and 5% glycerin The solutions were given for an hour t d s, the solution being nebulised in the Collinson or oxygenaire apparatus by oxygen at a rate of 8 litres a minute, which is equivalent to about 15 ml of the solution an hour Assessment of the patients consisted of two parts clinical assessment and measurement of viscosity of the sputum

Clinical Assessment

The patients were examined daily Inquiry was made about cough, dyspnœa, wheeze, and any difficulty in coughing up the sputum Physical signs in the chest were noted, special attention being paid to râles and rhonchi The amount of sputum for the 24 hour period was measured At the end of each weekly period an assessment of improvement was made (1) subjective improvement (i e, whether the patient felt better and could expectorate more easily after the inhalations), and (2) objective improvement (i e, changes in râles and rhonchi and a significant reduction in the amount of sputum produced daily)



Cone-and plate viscometer A, plate rotated by constant-speed electric motor B, cone suspended on phosphor-bronze wire C mounting of suspension wire D, light beam reflected from top of cone to circular scale

Viscosity of Sputum

Viscosity was measured in a cone and-plate viscometer specially designed and constructed for this purpose (see figure) It consists of a plate (A) rotated by a constant speed electric motor, a cone (B) suspended on a phosphor bronze wire, a mounting (C) of the suspension wire designed to ensure that the distance between the cone and the plate remains constant for each measurement, and a light beam (D) reflected by a small mirror on top of the cone to a circular scale The viscometer has a low rate of shear which is constant It has a wide range and is easily cleaned after each measurement The coefficient of variation was 2% with glycerin and 10% with sputum

TABLE I—25 PATIENTS WITH CHRONIC BRONCHITIS TREATED WITH AEROSOL THERAPY

—	Improvement		Viscosity of sputum decreased
	Objective	Subjective	
Period I			
No treatment	2	2	1
Period II			
Alevaire by aerosol	4	17	3
Period III			
Control solution by aerosol	6	18	[illegible]

To measure viscosity the gap between the cone and the plate is exactly filled with 2 ml of sputum from a syringe When the motor is turned on, the plate rotates at 1 r p m, and the cone follows the movement of the plate until the torque developed in the suspension wire is sufficient to overcome the viscous forces of the sputum After a few minutes to allow for stabilisation the deflection produced is read off the scale This gives the viscosity of the sputum, the deflection increasing with greater viscosity Since the method was developed to measure changes in viscosity instead of absolute values, the scale is marked in degrees

TABLE II—EFFECT OF VARIOUS AEROSOLS ON VISCOSITY OF SPUTUM

Aerosol	Viscosity of sputum (degrees of deflection)					
	Case 1			Case 2		
	Before aerosol	After aerosol	Reduction in viscosity (%)	Before aerosol	After aerosol	Reduction in viscosity (%)
Alevaire	137°	92°	32 9	210°	170°	19 1
Control solution	135°	81°	40 0	256°	195°	23 9
Saline solution	155°	100°	35 5	228°	188°	17 6
Water	132°	85°	35 6	230°	175°	23 9

Morning specimens of sputum were used because the viscosity of the sputum was greatest then The sputum was expectorated into a dry glass container and examined as soon as possible afterwards Spontaneous daily variations in viscosity were common, therefore the means of the viscosity measurements for each week were compared When the means differed by 20° or more, the viscosity of the sputum during that week was considered to have changed

Results

The results (table I) show that aerosols of alevaire and of the control solution are equally effective in bringing about considerable symptomatic improvement in patients with chronic bronchitis, the main effect being that the patients can expectorate more easily A few patients show objective improvement and changes in the viscosity of the sputum with either aerosol No significant change in the volume of sputum produced daily was found except in the few patients who showed objective improvement during the trial, and in these the sputum either diminished considerably or disappeared (Those patients who showed objective improvement clinically were not always those that showed changes in viscosity of sputum)

Medical Societies

MANCHESTER MEDICAL SOCIETY

Surgery in Portal Hypertension

AT a meeting of the section of surgery on Feb 12 Mr A G RIDDELL said that portal hypertension may be conveniently defined as a pressure in the portal system of more than 30 cm of saline In more than 70% of cases the cause is an intrahepatic block, while in the remainder it is thrombosis in the portal vein The mechanism of portal hypertension is obscure, but it occurs in about 30% of patients with cirrhosis, there is no very clear correlation between the portal pressure and the histological appearance of the liver. Neither portal hypertension nor œsophageal varices follow ligation of the portal vein in man, for in most patients an adequate collateral circulation develops Varices occur only when there is portal hypertension Splenomegaly results from portal hypertension leading to hypersplenism Hæmorrhage almost inevitably follows the appearance of varices, and in the presence of cirrhosis severe hæmorrhage leads to fatal hepatic coma This coma is said to be due to bacterial action on the ingested blood in the alimentary tract leading to ammonia intoxication Blood-transfusions are necessary to replace the *blood-loss* and to arrest the bleeding

The two problems in the surgical treatment of portal hypertension are control of the hæmorrhage and prevention of hypersplenism After an acute hæmorrhage, blood-transfusions should be started immediately and hæmorrhage controlled by an œsophageal tam eight hours is probably the limit for th treatment, and if hæmorrhage is still unco œsophageal varices should be ligated In th of further hæmorrhages portacaval and anastomoses are now established, and t mortality and the incidence of recurrent are low Percutaneous trans splenic p of great value in determining the type of After a successful shunt operation the and may completely disappear, while hypers may sometimes regress after a portacava Since the bleeding after splenectomy is the most problem in the surgery of portal hypertension tomy alone should never be performed in the of portal hypertension, if splenectomy is then it should be followed immediately by a s anastomosis

Prof A M BOYD referred to a series of 7 of the patients were alive and had not operation Mr H A HAXTON described who had had shunt operations, including later from liver failure and 8 who underwent anastomosis, including 3 who were now well

Dr M C G ISRAËLS reported a series observed by him and Dr J F Wilkinson, in w tomy had been done for splenic anæmia patients were still alive including 6 wh further bleeding, 3 had had one hæm had had two hæmorrhages and 2 *had* bleeding

Reviews of Books

The Physiology of Gastric Digestion

A H JAMES, D M Oxfd M D Toronto, M R C P senior lecturer in medicine Welsh National School of Medicine, and deputy director of the medical unit, Cardiff Royal Infirmary London Edward Arnold. 1957 Pp 192 28s

ONE of the fascinations of the study of gastric function is that advances can still be made with simple apparatus but those who begin in this way need a primer to orient them and to warn them of mistakes of experimental design and interpretation The practising clinician on the other hand needs a more general account of what is known about gastric function Both groups will be well satisfied with this book.

Dr James selects and interprets the literature of gastric function in such a way as to relieve us of the tedium of reading the original papers with unprepared minds and he assesses the opinions of different authors in a thoroughly constructive way A few hours with this book will provide a background of up to-date information and a stimulus to thought about its clinical application This transition should not be difficult because more than half of the figures refer to observations on man

This book will be valued by physiologists and clinicians alike

Sex in Christianity and Psychoanalysis

WILLIAM GRAHAM COLE London George Allen & Unwin 1956 Pp 329 21s

THIS is an admirable book. With learning and good sense the author examines a problem which is of manifest urgency in our Western society but which is commonly discussed in partisan style or with moralising superficiality Though theology is sometimes arid reading Professor Cole presents his material in vivid well-chosen language which holds the reader's attention He has one major theme he insists that the belief that the body is sordid a tomb for the soul did not derive from Pauline Christianity as many suppose, but from Hellenistic influences, at first Pythagorean and later Stoic and Epicurean at whatever point a study of Hellenistic culture begins dualism is encountered It was the presupposition of all thought and it was the soil in which the pale flowers grew Sex was regarded as low and degradi

He expounds this contention with much fo reviews in turn the writings of Augustine, Tho Luther, and Calvin, so far as they bear on se He next states the contemporary Catholic view, in the famous encyclical of Pius XI, *Casti Connu* large book by Father Messenger, *Two in* follows this with a necessarily less unifi contemporary Protestant views, for wh representative writers Leslie Weatherhea Princeton) Emil Brunner and Reinhold a Protestant theologian, Dr Cole is not Catholic doctrine in these matters, but to offer a fair statement of it

The psycho-analytic views about part 2 of the book are not limited Dr Cole reviews also the later devel Horney, Alexander, and Rado ha In a thoughtful and bold final chapt reconstruction of Christian interp applied to the conditions of modern issues of medical as well as religious

Educating Spastic Children

The Education and Guidance of F ELEANOR SCHONELL, M A PH fellow, department of pædiatric University of Birmingham Edin 1956 Pp 242 21s

THIS book gives the benefit of th experience with spastics in Aust Canada, the U S A, and, Carlson House School, Birmingha future Dr Schonell makes a plea integration between vocational tr in the case of the educable spasti in the case of spastics with su particularly those who are traina problem of the cerebral palsied ad into psychological and intelle spastics' and particularly the educational methods The book field and particularly to educat interesting and useful material

Clin Sci 1954, 13, 119
Physiol 1955 130 18P
Quart J Med 195
ancet, 1955 ii, 639

[illegible] ntral excretion [illegible] devised tubes for [illegible] se have not yet [illegible]

These me[illegible] mation on which present ideas [illegible] nia and iron-deficiency anæ[illegible] cious anæmia the evidence sho[illegible] ce of events is gastric atrop[illegible] production of intrinsic factor [illegible] to absorb vitamin B_{12} (extr[illegible] tine The serum-vitamin-B_{12} [illegible] eventually the clinical signs of [illegible] ear This sequence is known [illegible] There are, however at least tw[illegible] aloblastic anæmia In one the [illegible] *bothrium latum*) absorbs most of [illegible] ning the intestine and so deprive[illegible] itamin—a condition which has bee[illegible] Finland The other type is asso[illegible] orrhœa in which there is failure to ab[illegible] and sometimes failure to absorb vita[illegible] Witts points out that the anæmia [illegible] intestinal stenosis, or fistulas that leave [illegible] represents a combination of these two types [illegible] diversion of B_{12} and folic acid from the ho[illegible] the action of possibly abnormal bacteria, together with failure of absorption in the jejunum and the ileum In idiopathic steatorrhœa the anæmia is the result of impaired function of the small intestine (chronic jejunitis has been noted in the few recorded biopsy examinations[10]) And Girdwood's results[11] with folic acid excretion tests show that there is always failure of absorption of folic acid in this disease But some patients have diminished absorption of vitamin B_{12} as well, in contrast with pernicious anæmia, the administration of a source of intrinsic factor does *not* improve the absorption of vitamin B_{12} The few instances of neurological lesions in steatorrhœa, like those sometimes accompanying pernicious anæmia, must be due to this failure of intestinal absorption of vitamin B_{12}, there is no evidence that the stomach is involved

Witts remarks that "a generation after the discovery of the liver therapy of pernicious anæmia and the simultaneous revival of interest in iron deficiency there is still no shortage of problems for research" The clarification of our views of the ætiology of these anæmias and its relation to lesions of the alimentary tract has, however, already led to more efficient treatment

P.U.O.

The origins of fever are divided, like English social classes, into U and non-U The U in P U O stands for "unknown" in popular usage, but Har[illegible][12] maintains that the more hopeful and dignified meaning of "undetermined" was intended by the Army, who devised the term A third interpretation is "uncertain", and that is the word used in the official history of the 1914–18 war

Unexplained fever, whether it is of unknown or merely of uncertain origin, is a subject that needs reviewing every few years because it changes continually Not only do the diseases that [illegible] change their incidence, but the likelihood of [illegible] recognition alters too As soon as a condit[illegible] known as a cause of fever, it is less likely [illegible] as an explanation of obscure fever When a [illegible] condition is prominent in the list of causes of [illegible] obscure fever, the reason may be, not a high [illegible] but a high ignorance of the condition, so th[illegible] not being diagnosed as early as it might be [illegible] ledge of P U O is acquired by following cases [illegible] long as possible until a large proportion are di[illegible] and also by reviewing the case records wh[illegible] solution has been reached and asking "sho[illegible] and could this have been diagnosed earlier?"

There is no agreement on the time a fever [illegible] remain undiagnosed before qualifying as [illegible] over, patients cared for at home are less likely [illegible] diagnosed early than those who are admi[illegible] hospital soon after their fever begins As [illegible] expected, the picture of P U O in hospital [illegible] according to the time for which the conditio[illegible] remained obscure Of patients admitted with [illegible] nosed fever, over three quarters are diagnosed, [illegible] of those with fever still undiagnosed on dischar[illegible] three-quarters remain unsolved[13] It is from [illegible] that are finally if belatedly solved that clinicia[illegible] what to suspect in later cases (and half the [illegible] diagnosis is to develop the right kind of su[illegible]

Informative studies have been made by Bott[illegible] from the medical department of Karolinska Sjukh[illegible] in Stockholm, and Reid[14] at the Radcliffe Inf[illegible] Oxford Bottiger scrutinised the records of p[illegible] admitted with fever of unknown origin or [illegible] diagnoses, which comprised 2% of admiss[illegible] 1940 to 1949, and compared them with a[illegible] under the same diagnosis in 1954 to 1955 [illegible] 1 4%) The fall in the proportion of P U O cases [illegible] be significant, since the procedure relating to [illegible] diagnoses had been changed The most [illegible] diagnoses were non-specific infections (inclu[illegible] piratory and urinary infections, endocard[illegible] septicæmia) 31%, tuberculosis 11%, malign[illegible] ours 10%, and "collagenoses" 4%—of whi[illegible] three remained longer undiagnosed than the [illegible] 7 of the tuberculous patients had fever for a[illegible] of fifteen months before the diagnosis was [illegible] the malignant group (including Hodgkin's d[illegible] leukæmia) stomach, colon, bronchus, and ki[illegible] the common sites Renal cancer (hypern[illegible] of special importance, since there may be [illegible] pyelogram and no renal symptoms whatev[illegible] collagen group, Bottiger correctly emph[illegible] importance of electrophoretic examinatio[illegible] serum, which often reveals a suggestive [illegible] the gamma globulin fractions (estimati[illegible] sedimentation-rate is nearly as informative

Approaching the subject from a diff[illegible] Bottiger[16] analysed 4 solved cases of P [illegible] had remained a long time undiagnosed an[illegible] chose as representing four common [illegible] for P U O.

The first, to illustrate tuberculosis, was a [illegible] with pleurisy, fever, and hip pain for thre[illegible]

a story of a pleural effusion two years previously Normal radiographs, negative examinations for tubercle bacilli, and absence of response to a short course of antituberculous drugs seemed reasonable grounds for excluding tuberculosis, and antibiotics and cortisone were given till necropsy revealed the diagnosis four months later

The next 2 cases one of staphylococcal infection and the other of collagen disease, were more happily diagnosed —not by necropsy but by treatment A patient with staphylococcal endocarditis at length responded to erythromycin, and a sparse positive culture and a rising antibody titre were discovered And a patient with dermatomyositis responded dramatically to cortisone after red swollen areas over peripheral muscles and a positive skin biopsy had revealed the diagnosis

Bottiger's fourth patient was a 34-year-old woman with prolonged hectic fever and nothing helpful in the findings except a large liver and a leucocytosis of 35,000 She was naturally regarded as suffering from some form of infection until complete unresponsiveness to antibiotics suggested the diagnosis of Hodgkin's disease, which necropsy confirmed

These retrospective studies revealed no serious omission in diagnostic procedure, but they serve to show how uncertain investigations are as a means of excluding illnesses and how common illnesses like tuberculosis, blood-poisoning and cancer may lurk unobserved behind the spiked ramparts of obscure fever

Reid's findings,[14] based on 113 patients admitted to hospital with obscure fever, were very similar to those of **Bottiger** He found that among patients whose fevers remained unexplained for more than a month tuberculosis, tumours (including reticulosis) and infective endocarditis were the most likely answers **Reid** gave special consideration to his 6 patients with subacute infective endocarditis, none of whom when admitted, had murmurs, enlarged spleens, or anæmia He also examined the records of 50 other proven consecutive cases at the Radcliffe, and he found little evidence that splenomegaly cardiac murmurs, or anæmia were at all common Today subacute infective endocarditis is quite often seen among old people and the fever, weight-loss, and cachexia may be mistaken for evidence of malignancy and so not treated[17] The longest delay in diagnosis in **Reid**'s series was fourteen months and was accounted for by a hypernephroma This case, and others encountered in this country, show that **Bottiger** s accent on fever in carcinoma of the kidney is much needed Neither textbooks nor clinicians give it much place among causes of obscure fever, yet it is by no means rare It is interesting, too, that fever is not a sign of metastases, and removal of the tumour usually brings the fever sharply down

Other well known causes of obscure fever, such as brucellosis or simulation by thermometer juggling, were not very common in either the **Bottiger** or **Reid** series because these conditions are relatively familiar and are detected more or less quickly The importance of these investigations is that they bring to mind some of the less often suspected causes of fever and so make their early recognition more likely If tuberculosis septicæmia, collagen disease, and cancer (especially renal cancer) are carefully considered in all cases of obscure fever, many examples will be diagnosed earlier and others, though diagnosed late, will at least have been suspected early

Ammonia Metabolism and Hepatic Coma

Recent attempts to define the significance of high blood-ammonia levels in hepatic coma are important because of their influence on treatment The reproduction of the clinical syndrome in some patients with liver disease by the oral administration of complex nitrogenous substances from which ammonia can be derived suggests that ammonia intoxication is the cause of hepatic coma, especially since ammonium salts have the same action when given by mouth or intravenously Moreover, catheterisation of the hepatic vein has shown[1] that ammonia from the intestines may reach the systemic circulation by passing through a diseased liver or by way of portal collateral vessels, and this observation accords with clinical experience, which relates the onset of hepatic coma to inadequacy of liver function, the extent of the portal collateral circulation, or both[2] On the other hand, blood-ammonia levels often correlate poorly with the clinical condition in hepatic coma, and other toxic nitrogenous substances originating in the intestines may be responsible Blood-ammonia levels may therefore signify no more than the amount of ammonia that is permitted to accumulate in peripheral blood because of shunting " through portal collateral vessels and impaired ammonia metabolism in the liver and elsewhere

Ammonia in peripheral blood is derived largely from nitrogenous constituents of the diet by both bacterial and non-bacterial enzyme activity,[3] and urea synthesis in the liver is the most important way in which it is removed Smaller amounts of ammonia may originate in the lungs,[4] kidneys,[1] and brain[5] under certain circumstances, and the peripheral tissues and the brain can extract ammonia from the blood The poor correlation between ammonia levels in peripheral veins and the neurological state in hepatic coma has been attributed[6] to the arteriovenous ammonia difference due to peripheral uptake of ammonia In the experience of **Bessman** and **Bessman**[6] arterial ammonia levels are closely related to the state of consciousness, and they suggested that ammonia uptake in the brain in hepatic coma causes a defect in intermediary metabolism because the ammonia withdraws α-ketoglutarate from the tricarboxylic acid cycle in the brain Later work by **Summerskill** et al[7] suggested that arterial ammonia levels often reflect the amount of nitrogenous material *in the intestines rather than* the neuropsychiatric state They confirmed that ammonia is used by brain and peripheral tissues but showed that the uptake of ammonia by the brain and tissues is impaired in liver disease particularly in hepatic coma They concluded that hepatic coma results from a direct toxic action of ammonia on the brain secondary to *failure* of cerebral ammonia ' uptake " Furthermore a defect in intermediary metabolism due to ammonia was demonstrated by the production of high blood-pyruvate and α-ketoglutarate

levels in patients with liver disease who were given intravenous ammonium chloride—a finding which could explain the raised levels of these keto-acids in spontaneous hepatic coma

Treatment of hepatic coma is first directed towards correcting factors which may have precipitated coma—such as gastro intestinal hæmorrhage, intercurrent infection, high-protein feeding, and drugs, including methionine and ammonium salts Acetazolamide ('Diamox') has also been shown to cause hepatic coma, and raised blood-ammonia levels,[8] because it impairs ammonia uptake by peripheral tissues[9] This finding emphasises the importance of ammonia metabolism at other sites when the liver is failing in this way, and supports the view that toxic effects spring from interference with ammonia uptake rather than ammonia utilisation A reliable method of treatment recommended by SHERLOCK et al[2] includes elimination of nitrogenous material from the diet, oral broad-spectrum antibiotics (of which neomycin is the most effective),[10] and enemas This routine proved superior to other measures in a large series of patients[11] and, while reducing blood-ammonia levels,[7] it also has the merit of eliminating from the intestines other nitrogenous substances of possible toxicity Glutamic acid,[12] which can combine with ammonia to form glutamine, has been given in the hope of removing ammonia already in the body, but the results have been disappointing[13] MCDERMOTT et al[14] found glutamic acid of benefit when liver function was adequate, but such patients have a relatively good prognosis anyway In more severe liver disease the effect of glutamic acid on blood-ammonia and clinical state is transient A trial of aspartic acid yielded similar results[11] Lately, NAJARIAN and HARPER[15] have shown that arginine lowers peripheral-vein ammonia levels in man and that it may be of value in hepatic coma[16] Most of their patients went into coma because of hæmorrhage or intolerance of nitrogenous substances, and they therefore had a relatively good prognosis, but the recovery of 2 patients from coma due to serum hepatitis is very significant Since the action of arginine depends on its function as a precursor of ornithine in the Krebs urea cycle in the liver, its success in hepatic failure is hard to understand, and the possibility remains that coincident treatment, such as protein withdrawal or antibiotic therapy, may have been responsible This consideration applies to the appraisal of any treatment in hepatic coma and, combined with unpredictable fluctuations in clinical progress, it partly explains the disagreement about what a particular treatment can do

Thus, on both therapeutic and biochemical grounds, ammonia intoxication has not been conclusively incriminated as a cause of hepatic coma Nevertheless, now it is known that the syndrome includes various clinical sequences, it is reasonable to attribute to ammonia intoxication those components which can be reproduced by giving ammonium salts to patients with liver disease Apart from rare successes with lipoic acid[17] (which facilitates the oxidation of α-keto-acids in the citric acid cycle) and cortisone treatment of the neurological disorder is ineffective when hepatic coma results from progressive liver failure alone In such circumstances the prognosis is grave, since severe hepatic disease permits widespread metabolic disturbance, and measures directed solely at the neurological disorder will not improve liver function, upon which survival depends In contrast, coma due to intolerance of nitrogenous substances responds dramatically to protein withdrawal and antibiotics[18] Most patients fall between these extremes, and results may well be improved by the addition of specific drugs, of which the latest is arginine, to a basic regimen of careful clinical management, protein withdrawal, and neomycin

Cytological Detection of Uterine Cancer

THE method of detecting malignant disease of the uterus by the recognition of cancer cells in a vaginal or cervical smear has been in use in many centres for some fifteen years, and many different techniques for collecting the cells have been described[19] Rather surprisingly there is no very general agreement about the value of the method Views differ partly because of the different ways in which results have been reported, and partly because accounts of false positives and false negatives have caused confusion, but the main reason perhaps is that many of the reports do not make it clear how often cytology has really helped to make the diagnosis Carcinoma of the cervix can all too often be diagnosed clinically without any reasonable doubt the first time the patient is seen by the gynæcologist Less often, a confident diagnosis is impossible, though there are definite grounds for suspicion In both cases biopsy is imperative, but when the clinical diagnosis is uncertain the cancer may involve only a tiny part of the cervix, and the tissue removed may not include a sample of the malignant area unless multiple specimens are taken or the whole of the squamo-columnar junction is removed, which is by no means always done Under these circumstances, the examination of smears is a great help, and both GRAHAM and MEIGS[20] and DARO et al[21] found the smear diagnosis more accurate than punch biopsy in early carcinoma of the cervix

But it has been repeatedly shown in recent years that early invasive carcinoma, and particularly in situ carcinoma of the cervix, can be present without symptoms or signs in any way suspicious of malignancy, and even if the patient is examined by her doctor, biopsy will seldom be advised Without the aid of cytology this type of cancer will be diagnosed either by chance or not until later in the disease We do not know how common this form of malignancy is, so it is hard to assess the true value of cytology cytological methods have often been given credit for the diagnosis without any clear indication of the quality of the clinical screening of the cases. McLaren et al[22] have lately described their experiences with vaginal cytology in Birmingham, where great care was taken to establish clearly whether there were grounds for suspecting cancer or not. Of 2250 women attending the outpatient department there were 10 in whom the diagnosis of carcinoma or carcinoma-in-situ was made without any previous clinical suspicion of the disease. Anderson et al[23] reported a higher incidence (1.1%) of unsuspected cervical carcinoma, but it was not certain that their patients had always been subjected to as searching a clinical inquiry as those of McLaren et al. These figures suggest that, if cytological methods of diagnosis are to be applied to groups of women in whom there is no reason to suspect uterine cancer, early carcinoma (chiefly non-invasive) might be found as often as once in 100–250 women. Unsuspected carcinoma of the body of the uterus would probably be discovered much less often than cervical cancer, for most patients with carcinoma of the body have suspicious symptoms which prompt complete investigation. But if unsuspected cancer is, in fact, as common as this, there is much to be said for Osborn's[24] view that this kind of cytology is more rewarding than many other investigations regarded as essential in a general pathology laboratory. Further careful studies are needed, both to confirm the incidence of truly unsuspected cancer, and to extend our knowledge of the behaviour of in situ carcinoma so that its correct treatment can be established. As McLaren et al point out, cytology can uncover a disease at a stage when we have no exact knowledge of its natural history and, therefore, of its implications for the individual patient.

But if vaginal cytology is to be extended as a screening procedure, which women should be examined? It is clearly impracticable, even if it were desirable, to screen all women at regular intervals, and one view is that if we cannot examine all, we should examine none. Moreover, when a patient who has attended a cancer-detection clinic is asked to return because of a doubtful smear, fears may be sown in her mind that are hard to allay, and more harm than good may result. There is no such objection to the use of vaginal smears in women already attending a gynæcological clinic, who would normally be asked to return for a follow-up visit in a few weeks' time. If it were used in this way, and combined with carefully gathered clinical data, much more would be learned about the value of this investigation. Until there are more trained cytologists, the method might perhaps be restricted to patients awaiting a major gynæcological operation, a few of whom might thus avoid the inadequate operation of simple total (or even subtotal) hysterectomy, or amputation of the cervix, when early carcinoma of the uterus was, in fact, present unknown to the surgeon. Wachtel and Plester[25] described 2 cases in which cytological examination modified the proposed operation; and Speert[26] recorded 14 examples of unsuspected cervical carcinoma in surgical material removed for other reasons.

Nevertheless, however valuable cytology may be in detecting cancer when it is not suspected, it must not be allowed to become a substitute for clinical investigation; for there are other diseases than cancer and other organs than the uterus are subject to cancer. The diagnostic error of cytology is by no means negligible, nor is it likely to become so; Osborn considers that vaginal cytology alone is certain to miss about 10% of cases of cancer of the uterus. Whenever clinical suspicion of cancer arises, therefore, other investigations, particularly biopsy and curettage, are necessary in addition to a cytological examination, if the chances of missing the diagnosis are to be reduced to a minimum.

Annotations

REMUNERATION

Instead of arranging an increase through the Whitley Council, as they had proposed, the Government last week announced that the salaries of junior hospital doctors and dentists are to rise by 10% from April 1. This is the second increase for junior hospital doctors since 1948, and according to an analysis in the *Financial Times*[27] it gives the house-physician or house surgeon nearly (though not quite) the same purchasing-power as he had when the service started. But though the houseman will have a gross salary 33.5% higher than in 1948, to compensate him for a rise in prices estimated at 36%, the senior registrar will still have to manage on a salary only 21% higher than he had eight years ago. The *Financial Times* correspondent points out that, on the new scale of salaries offered to university staffs (without any direct pay claim) in order to maintain recruitment, non medical professors will have their salaries increased by about 50% since 1949 and clinical professors by 9%, against a price rise estimated at 34%.

The claim for a 24% increase on existing remuneration, put forward last year on behalf of all doctors in the National Health Service, was based on evidence that prices generally were 24% higher in April, 1956, than in April, 1951. Though, until the Royal Commission reports, there can be no hope of any settlement based on principle or on detailed consideration of the facts, we trust that the further "interim adjustment" of which the Prime Minister has promised to speak "in due course" will be one that reasonable people will think reasonable—at any rate in the present difficult circumstances of the nation.

THROMBOSIS OF THE PULMONARY ARTERIES

Pulmonary heart disease resulting from thrombotic occlusion of the small pulmonary arteries by repeated embolism has been recognised for some years; but massive thrombosis of the larger pulmonary arteries is a less familiar cause. For this reason, the findings of Ball et al[28] who have added 23 new cases to the 200 already on record, are particularly welcome.

In all but 4 of their patients the thrombosis was associated with some other disease (mitral stenosis, chronic bronchitis, and carcinoma of the lung, stomach, or pancreas were predominant). At necropsy the pulmonary thrombosis was usually found to be secondary to pulmonary embolism, but in a few cases it was primary. The criteria for this distinction between primary and secondary pulmonary thrombosis are not entirely satisfactory, but primary thrombosis is suggested by local disease of the artery wall, by the fact that the thrombus forms a perfect cast of the pulmonary artery, often showing laminations parallel to the vessel wall, and by the absence of any source for an embolus. Thrombosis secondary to embolism is likely when there is no disease in the artery wall, and when there is a source for the embolus, which is often coiled, not forming a perfect cast of the pulmonary artery but bearing the impress of the vessel from which it arose. Pulmonary infarction beyond the occlusion was a variable finding and did not help to distinguish the two conditions.

The clinical features were commonly those of right-sided heart-failure with low cardiac output. The onset was often insidious. Dyspnœa was prominent, and was commonly accompanied by pleural pain and hæmoptysis, suggesting pulmonary infarction. Some patients were liable to faint, especially on exertion, and several died in coma. The principal signs were those of right ventricular hypertrophy, but in some patients this was due to concomitant mitral stenosis. A pulmonary systolic murmur, a normal or soft second heart sound, a small pulse, and cyanosis were also noted. Radiologically, an enlarged right ventricle and dilated pulmonary arteries, often with diminished pulsation, were the main findings. The lung fields were sometimes oligæmic or contained shadows caused by pulmonary infarction. The electrocardiogram usually reflected the pattern of right ventricular hypertrophy.

The rare diagnosis of pulmonary-artery thrombosis must therefore be considered whenever a patient has unexplained congestive failure, breathlessness, fainting, or repeated attacks of chest pain and pulmonary infarction. If the clinical picture includes evidence of peripheral venous thrombosis, a systolic murmur in the pulmonary area, and a normal or soft second sound, then the diagnosis becomes more probable. If in addition there is radiological evidence of an enlarged right ventricle, dilated pulmonary arteries without significant pulsation and clear lung fields (or shadows of pulmonary infarction), and if the electrocardiogram indicates right ventricular hypertrophy, the diagnosis becomes almost certain.

When the diagnosis is made, a long period of anticoagulant treatment offers the only hope of preventing the thrombus from extending. If emboli are repeatedly arising from the leg veins and cannot be controlled by anticoagulants, ligature of the inferior vena cava may have to be considered.

A MATTER OF COMPLICATION

THE significance of complications following an operation or an acute illness has been much reduced by greater control of infection and by the precautions taken to prevent cross-infection in hospitals, particularly in childrens' and infants' wards, where infection may strike with disastrous speed. Similar, but less elaborate, precautions are taken in acute geriatric units, for infection can be equally hazardous at the other extreme of life. Rang[1] has lately examined the incidence of complications among patients in the geriatric unit of University College Hospital, London, during a 12-week period. These complications may be considered to be immediate, as opposed to remote. Rang found that one complication occurred in each geriatric bed every 79 days, compared with a complication interval of 298 days in an acute medical ward and 282 days in a halfway house. Moreover 68% of patients in the geriatric unit had complications compared with 9% among general medical admissions. The average age of the general medical admissions was 58, and in Rang's over-65 group age did not seem to affect the incidence of complications; why then was there this disturbing difference?

Much depends on what may reasonably be accepted as a complication. The *Shorter Oxford English Dictionary* attributes to John Arbuthnot (1667–1735) the original medical interpretation of "disease complicating other diseases." *Webster* and *Chambers* agree on a succinct non-medical meaning, "intricate blending or entanglement," and *Chambers* defines complications in the medical sense as "a number of diseases present at the same time." In Rang's survey, only conditions arising after admission and not clearly related to the patient's original illness were counted as complications. But "a number of diseases present at the same time" is the lot of many old people, and most of those who are admitted to hospital are probably "complicated" from the outset.

In whatever way an illness in an old person may arise, it is always hard to be sure that a set-back under treatment does not come within the natural history of the initial acute episode or that it is not due to aggravation of some latent condition. For example, if an old man is admitted stuporose after a cerebrovascular disturbance, severely dehydrated from any cause, or in congestive failure, the rapid onset of chest infection is an immediate probability and hardly a complication; but if a pneumonia develops after recovery from the acute phase, then it must be regarded as a complication, provided the patient's lungs were normal for his age before the vascular accident. On the other hand, if he had chronic bronchitis, quiescent at the time of the acute illness, then a sudden flare-up at any stage is a hazard of bronchitis and cannot be regarded as a complication of the cerebrovascular disease. Again, an elderly obese diabetic, who long since stopped visiting the clinic because of blindness and osteo-arthritis, is admitted with skin sepsis, a urinary infection, and heavy glycosuria. The day before she is due to be discharged, she has a cerebral thrombosis. Is this to be regarded as a complication of her diabetes or as a dissociated manifestation of cerebral arterial disease, the association with diabetes being fortuitous? Is it logical ever to regard a coronary thrombosis in the elderly as a complication, except as a calculated risk when using certain drugs? All this may seem to be a splitting of hairs, but it is nevertheless true that the presenting illness often takes the form of a complication of pre-existing disease. Senile osteoporosis often has no symptoms until a vertebra collapses; a subsequent bedsore would be a further complication, a hæmatemesis from an unsuspected gastric ulcer would not. For these reasons, the picture given by Rang's figures may be too gloomy.

Rang classes together falls and confusion because he considers they are partly due to the same thing. Certainly, a confused elderly person may easily fall if not carefully supervised, but falls in hospital are not uncommon in the mentally composed. In many hospitals the floors are uneven and worn, ready to trip, or polished to ice-rink slipperiness. Along these floors shuffle the old folk, shuffling because of slippers which do not fit, because of a nightdress which has to be twisted and held, or because of a trailing dressing-gown. Since every old lady in hospital rightly insists on carrying her hand-bag, her knitting, and perhaps a library book, morning paper, and spare blanket on her way to the day-room, it is surprising that many of them stay on their feet for as long as they do. No form of mental disturbance other than confusion is included in Rang's analysis, so presumably the term covers all mental disturbance which can be handled in an acute geriatric ward. Thus, patients who become confused shortly after admission may be delirious because of the increasing severity of their illness—a complication common to any age. It must be distinguished, among other things, from a confusional state due to cerebral arteriosclerosis, which may be precipitated by acute illness or by unfamiliar surroundings, but whose underlying cause has been present for years it seems wrong to regard the first clinical manifestations of such a condition as the complication of a dissociated illness.

---

[1] Rang, M. *Lancet*, Feb. 23, 1957, p. 401.

For the 26 old people in the halfway house attached to University College Hospital the average stay is measured in years. Their complication interval of 282 days will not surprise a geriatrician who looks after a halfway house or a long-stay ward for the infirm elderly, or who maintains close association with welfare homes. In these sheltered surroundings, the old people live contentedly on for years and then one day quietly depart. Before they enter a halfway house or long-stay ward many of these patients have been in an acute geriatric unit, in all probability with an illness punctuated by setbacks—or complications. When everything that can be done has failed to restore them to independence, they must enter a new phase of life, in which it is often happily rare for episodes of acute illness to disturb the downward path.

Unless we regard most elderly patients as "complicated" because of processes involved in tissue degeneration it may be simpler to accept some setbacks as inevitable in their management, rather than class them all as complications. Whatever the accepted interpretation of his findings Rang's inquiry provides a valuable stimulus and emphasises the great care called for in the management of acute illness in the aged.

TUBING FOR INTRAVENOUS INFUSIONS

TRANSFUSION of blood and infusion of solutions containing electrolytes glucose, and other substances into a patient's veins have become commonplace, but it need hardly be said that they are not without their complications. A blood-transfusion sometimes causes a reaction and a rigor when there is no question of mismatching of blood-groups and no unusual antibodies. Even the infusion of a simple saline solution has been known to cause similar reactions. Another and more serious sequel of intravenous infusions is thrombophlebitis, which may lead to permanent occlusion of a vein—no light matter for a patient needing multiple transfusions. Even though everything has been done to ensure that the fluids infused are properly prepared, thrombophlebitis may still ensue. Suspicion has fallen on the tubing used to connect various parts of the apparatus—particularly the red rubber tubing used, and re used, in the standard giving-sets issued by the National Blood Transfusion Service. The Medical Research Council's blood-transfusion research committee have been investigating this matter and their report appears on p 595.

They begin by noting that according to recent reports, the incidence of thrombophlebitis using N B T S sets is over 50%, *when the infusion is continued for more than twelve hours*. Handfield-Jones and Lewis[1] had shown that the incidence of thrombophlebitis was much less when a pure latex rubber tubing was substituted for the red rubber tubing. The committee therefore arranged for a number of centres to carry out a comparative trial between N B T S sets and a plastic infusion set of "disposable" type. The set used 6 feet of plastic tubing, ending in a short length of latex rubber tubing fitting on to the intravenous needle, the drip chamber and filter chamber were plastic and the filter itself of nylon mesh. A special rubber bung with an air inlet valve was provided for fitting into the standard 540 ml blood-bank bottles.

In the opinion of the committee the trial showed conclusively the superiority of the plastic set over the standard red rubber and glass set. Reactions were still seen with infusions lasting over twelve hours, but in only 32% of patients when plastic sets were used compared with 56% with the red rubber sets. There were severe and very severe reactions in 18% of patients when plastic sets were used, and in 34% with rubber sets. The results also confirm once again that the longer the infusion continues, the greater the risk of thrombophlebitis, and that infusions lasting less than twelve hours carry a negligible risk. This does suggest that the properties of the tubing are not the sole factor in the production of thrombophlebitis.

Thus there now seems to be good evidence for abandoning the use of red rubber tubing for giving-sets. But to replace the thousands of N B T S giving sets by disposable plastic sets would be very costly. These disposable plastic sets are popular in the U S A, and they are used with a plastic bag holding the blood or infusion fluid, or with glass bottles fitted with a special bung into which the plastic piercing-needle can be inserted. The British sets have a special bung and metal cap to fit the N B T S bottles, and to throw these away each time seems unnecessarily wasteful. The alternative is to replace the red rubber tubing in the present N B T S sets by a safer form of tubing. For this purpose, two types of tubing are available—the pure latex rubber tubing advocated by Handfield-Jones and Lewis, and the silicone-rubber tubing whose properties have been investigated by Wilkinson et al.[2] The silicone rubber was found to be particularly suitable for intravenous infusion work. Wilkinson et al.'s results cannot be compared with those of the M R C committee, because Wilkinson et al were working with blood-transfusions and consequently the tubing was not in use for periods of over twelve hours. Nevertheless it is interesting to note that in 296 transfusions given through silicone tubing, there were only 3 reactions. Silicone tubing has the considerable advantage that it can be used over and over again, specimens of silicone tubing were washed and autoclaved over forty times before showing signs of deterioration.

If silicone tubing proves as safe as plastic tubing for more protracted infusions, the choice may well turn on cost. Latex tubing costs two to three times as much as red rubber tubing, silicone tubing will probably be two or three times the price of latex tubing but the silicone tubing can be used forty times compared with about six times for latex tubing. The disposable plastic sets probably cost as much as a length of silicone tubing for a single transfusion set. We hope it will soon be possible to take an official decision in this matter. Departments anxious to keep transfusion reactions to a minimum abandoned red rubber tubing some time ago, and the M R C committee's report will encourage more people to do so.

CYTOMEGALIC INCLUSION DISEASE

INTRANUCLEAR inclusions in very large cells were first described in the kidneys of a stillborn infant more than fifty years ago.[3] Similarly affected large cells are often found in the salivary glands of young children at routine necropsies, the incidence varying in different series from 10 to 32%.[4]

In 1920 Jackson[5] described abnormalities in the ducts of guineapigs' salivary glands which she attributed to a protozoon. But soon afterwards it was shown[6] that these lesions, which resembled those found in the salivary glands of children[4] were caused by a virus resistant to 50% glycerol and capable of passing through a Berkefeld N filter. Similar agents, all species specific and all causing the same morphological abnormality, have been recognised in rats, mice, moles, hamsters, monkeys, and chimpanzees By analogy it was inferred that the human lesions were caused by a virus and the group of agents came to be known as salivary-gland viruses In 1954 Smith[7] reported that she had propagated the mouse virus in culture of mouse embryo fibroblasts, in which the characteristic lesions could be seen Her culture fluids caused the salivary gland lesions to appear in mice *of a strain not naturally carrying the virus, and they also* infected new cultures Last year[8] she described the successful infection of cultures of human uterine wall with virus from the salivary gland of a seven-month infant and from the kidney of a one-month infant The cultured cells showed the characteristic lesions and could be protected by human immune sera The infective materials which caused these lesions in human cells could pass bacteria-retaining filters and had no effect on suckling mice or cultures of mouse embryonic tissue

It is thus well established that the presence of abnormally large cells with intranuclear inclusions in the salivary glands and other organs of infants is due to infection with a species specific virus Why this abnormality occasionally becomes a generalised fatal disease is not known Smith and Vellios[4] found the generalised disease in 1% of 1400 necropsies, and they concluded that this was a primary fatal disease in infants under two months of age The clinical picture was usually the result of damage to the liver and hæmopoietic system In older infants generalised cytomegalic inclusions were more commonly associated with some other primary illness Cappell and McFarlane,[9] in a beautifully illustrated account of the pathological changes, emphasise the importance of thinking of this infection in hæmolytic disease when isoagglutinins cannot be found The generalised disease has been described in adults[10], but Hamperl,[11] examining material from such a patient, thought to have died of inclusion pneumonitis, was able to demonstrate the presence of *Pneumocystis carinii*, and he thought that cytomegalic virus alone could not cause pneumonitis in adults

As the kidneys of infants were involved in the generalised disease and the characteristic large cells could be seen in the lumen of the tubules, Wyatt et al[12] suggested that it might be possible to diagnose the disease during life by finding such cells in the urine, and in this way Fetterman[13] later made the first confirmed antemortem diagnosis of the disease Margileth[14] described the care and treatment (which included cortisone) of a patient who survived an established generalised infection Birdsong et al[15] have lately recorded 2 cases, 1 of them fatal, in which prednisolone and later corticotrophin were given They think that in future exchange transfusion should be considered In the child who survived, examination of urinary sediment had confirmed the diagnosis

Birdsong et al suggest that the mother of an infected infant must have an initial subclinical infection during her pregnancy—a view which is supported, they think, by the fact that the mothers are often primigravidæ from isolated rural homes. But Smith and Vellios[4] mention an example in a fourth child, and Wyatt et al[12] say that no inclusions are found in the placenta Like Wyatt et al and Bacala and Burke,[16] Birdsong et al say that symptoms and signs in the generalised disease depend on the tissues principally involved and may include jaundice, hepatomegaly, purpura, splenomegaly, thrombocytopenia, hæmolytic anæmia, and, less commonly, evidence of intracranial calcification or cerebral hæmorrhage

SALMONELLÆ IN REPTILES

IT has been known for several years that some lizards snakes, and tortoises harbour members of the genus salmonella, but knowledge has advanced slowly because reptiles, as a tribe, are hard to find or hard to catch In the course of an inquiry into the distribution of salmonellæ in Ibadan, Collard and Montefiore[1] got over the second difficulty by employing schoolboys with catapults to collect specimens of *Agama agama*, the lizard which basks on every sunny wall in Nigeria Their enthusiastic Nimrods made a bag of 160 of which 11% were found to carry some species of salmonella in their bowels All but two of these species had been isolated previously from the human inhabitants of the town That no salmonellæ were found in 100 gekkoes (*Hemidactylus boothii*) taken at the same time may be an equally important observation Collard and Montefiore suggest that the lizards acquire infection by snapping up flies as they leave the trench latrines, while the gekkoes (which also eat flies) prefer the dark insides of buildings This implies that flies soon lose their burden of excrement or that flies from latrines do not enter houses It may be that the two reptiles have not the same taste in edible flies It is curious too that Mackey[2] in East Africa quite often found salmonellæ in a related gekko

The distribution of these organisms in reptiles is in fact, puzzling Many of the recorded isolations from snakes are from single animals, either found dead or sick or else in zoological gardens where there is often a risk of infection from some other captive Negative findings are more common than the published records suggest Since all snakes are carnivorous, they are liable to infection from their victims and this might explain the simultaneous infection of gopher snakes and turkey poults recorded in Arizona[3]

Testudo græca, the tortoise kept as a pet, is a complex of about seven sub species all native to the Mediterranean basin It is vegetarian but, whether wild or in captivity, over 90% of the specimens examined have yielded one or more species of salmonella Other species of testudo in Asia, Africa, and South America have produced very few, but the species of salmonella found have been the same as those found in *T græca* All other tortoises and terrapins examined have so far given negative results, and as far as is known no other reptile shows a carriage rate approaching that of *T græca* At the same time anyone who has examined reptilian fæces must have noticed the abundance of unnamed bacteria which seem related to salmonellæ either in biochemical behaviour or serological affinities

It is customary to speak of reptiles which harbour salmonellæ as "reservoirs of infection" Apart from the fact that man and reptiles seldom have intimate relations, the phrase may indicate a too anthropocentric view If Collard and Montefiore are right in their surmise on the source of infection in lizards, it would be more accurate to describe man as a reservoir of infection for reptiles Mackey may be right in suggesting that human food is contaminated by dust containing the fæces of infected lizards, but in many old houses man lives in more or less contented symbiosis with mice without being infected by these notorious carriers Who infects or who is infected by the solitary tortoise sunning himself in the maquis? The epidemiology of salmonella infection has been confused by a great number of attractive analogies and hypotheses, few of which have been and some of which cannot be proved

INFECTION of wounds and burns in hospital depends on many factors One of these is the accumulation and distribution of pathogenic organisms by bedding materials Blankets and sheets on the bed of an infected patient, when examined by a suitable method such as the sweep plate technique, can be shown to harbour large numbers of the responsible pathogen (Blowers, Mason Wallace, and Walton 1955) Other methods can be used to show that these organisms are scattered far and wide whenever the bedding is disturbed Normal laundering does not sterilise blankets, and, after washing, some of them are more heavily contaminated than before This is not surprising since woollen materials are washed at a low temperature (about 37°C) to prevent shrinking and "felting" An ordinary laundry rotary machine does little more than redistribute bacteria between the individual blankets Cotton articles, such as sheets are usually boiled and steam-pressed in the laundry and these processes destroy most pyogenic micro-organisms

In any serious attempt to prevent cross infection of wounds hospital blankets must therefore be sterilised regularly This can be done by exposing them to steam, but after a few such treatments even at low pressure they have shrunk to some two-thirds of their original length and lost all their fluffiness The result is a small, hard, and uncomfortable article Repeated laundering even without sterilisation eventually gives the same result Shrinking due to ordinary washing can be reduced if the blankets are specially treated when new, but this does not protect them against high temperature sterilisation The cost of a 5 lb (2 3 kg) hospital blanket 96 × 72 in (244 × 183 cm) is £2 10*s* , or £2 15*s* if anti-shrink treatment is applied, so that replacement costs are high if sterilisation and washing are done as a routine In many hospitals, therefore, blankets remain not only unsterilised but unwashed for long periods

To overcome some of these difficulties various methods have been suggested van den Ende, Lush, and Edward (1940) devised a process for treating blankets with oil so that bacteria stick to the fibres instead of being scattered during bed-making Formalin disinfection is used, especially in infectious diseases hospitals, but there has always been some uncertainty about its efficacy Also it needs expensive equipment and each article has to be handled separately which increases labour costs Disinfection of blankets with quaternary ammonium compounds has been suggested (Rountree 1946, Barnard 1952, Blowers and Wallace 1955) This is highly efficacious against the pyogenic cocci, but its action against *Pseudomonas pyocyanea* is poor and against tubercle bacilli doubtful It causes less shrinking and felting than does steam sterilisation and blankets can be treated some thirty times before they have to be discarded We have found it the most satisfactory method for disinfecting woollen blankets and will continue to recommend it so long as they are used It seemed to us, however, that the right answer would be to make blankets of a material that could be boiled without serious damage Most laundries have facilities for high-temperature washing, and, if blankets could be treated in this way, all non-sporing bacteria, including tubercle bacilli and pseudomonas, would be destroyed and separate sterilisation would not be needed We therefore made preliminary trials of several materials Those showing enough promise to warrant longer trials were

1 Turkish towelling
2 Loomstate cotton weave
3 Synthetic polyester fibre ('Terylene')

New Materials

The first two materials were tried in a plastic-surgery and burns unit where unsterilised woollen blankets had previously been used Because wound infection was already a problem in the unit, it was decided to make a complete change to sterilised blankets As it was not possible to have wards fully equipped with each of the new types of blanket, it was arranged that wool, towelling, and loomstate would be used successively, each for a week This made it easy for patients and nurses to compare the three materials At the end of each week, when the change over was made, the dirty blankets were sent to the laundry and washed Woollen blankets were washed at 37°C and then treated with a quaternary ammonium compound , towelling and loomstate were washed at 100°C but without chemical treatment

The terylene blankets were tried in a surgical ward of a tuberculosis hospital Only 6 were available, so they were used and treated as part of the normal blanket stock except that they were washed at 100°C

Turkish Towelling †

This is a heavy material of the type used for bathing-wraps It is white and has a clean and pleasing appearance Each blanket measures 100 × 80 in (254 × 203 cm), weighs 5 lb (2 3 kg), and costs £3 6*s*

The patients were satisfied with the warmth and comfort of the towelling and found it equal in all respects to the usual woollen blanket The nurses found it easy to handle , visitors and administrative nursing staff commented on the neat and clean appearance of the beds made up with the new blankets

After several months' use 6 blankets were examined bacteriologically by the sweep-plate method before and after laundering The results are shown in the table together with those of 6 chemically treated woollen blankets We also include, for comparison, results from woollen blankets in another ward , these were washed in the ordinary way without sterilisation

After twelve months and twenty launderings the Turkish towelling blankets were 98 × 78 in (250 × 198 cm), an area-loss of 4% due to shrinkage The woollen blankets, originally 96 × 72 in (244 × 183 *cm*) had shrunk to 78 × 58 in (198 × 147 cm) The area-loss was thus 35% But the most striking difference between the two materials was that whereas the towelling retained its original texture almost unimpaired, the woollen blankets had become felted and hard and were nearing the end of their useful life A few towelling blankets have been used on ward and theatre trolleys for a longer period and have been washed over fifty times These, too, are still in excellent condition.

Loomstate Cotton Weave ‡

This is similar in appearance to the cellular woollen material that is already on the market It has a cream colour and is made into blankets 96 × 76 in (244 × 193 cm) weighing 3 lb (1 4 kg) and costing £1 0*s* 10*d* each These were a little less warm than the woollen and towelling blankets and some patients needed four of them instead of the usual three Bacteriological tests

GENERAL BACTERIAL COLONY-COUNTS ON SWEEP-PLATES FROM SIX BLANKETS OF EACH MATERIAL BEFORE AND AFTER WASHING

Wool (37°C wash)		Wool (37°C wash + quaternary ammonium rinse)		Towelling (100°C wash)		Loomstate (100°C wash)		Terylene (100°C wash)	
Before washing	After washing	Before washing	After washing	Before washing	After washing	Before washing	After washing	Before washing	After washing
Over 2000	Over 2000	960	4	570	2	751	1	500	[illegible]
Over 2000	776	523	2	500	10	301	3	478	3
Over 2000	740	311	0	500	5	280	1	227	3
972	860	199	2	220	2	223	8	157	0
622	1028	101	4	85	2	138	1	77	1
279	752	88	1	67	2	119	2	63	0

were satisfactory (see table), and after twelve months' use and twenty washings the blankets measured 94 × 74 in (238 × 188 cm), having lost only 5 % of their original area Texture was unaltered

Terylene §

This now well-known and versatile material § is made into a staple fibre and woven to make blankets almost indistinguishable from a high-grade wool Each is 89 × 74 in (226 × 188 cm), weighs 3½ lb (1 6 kg), and costs £3 18*s* In warmth and appearance these blankets are equal to new woollen ones After eighteen months' use and thirty washings the measurements were 84 × 72 in (214 × 183 cm) with an area loss of 8 % The material is now rather less fluffy than when new, but is in vastly better condition than a woollen blanket after the same use The effect of boiling on the bacterial flora of terylene blankets is shown in the table

Discussion

We believe that patients in hospital are entitled to bedding that has been washed and sterilised since it was last used Moreover, it seems wrong that after a wound has been covered with sterile materials in the operating-theatre, the patient should be returned to a bed of heavily infected blankets We regard the bedclothes as part of the patient's wound dressing and think that they should be free from pathogenic organisms In surgical and infectious diseases wards, at any rate, all bedding should be changed and sterilised weekly to reduce dissemination of organisms during bed making All this can easily be done with the new materials that we have tried because they can be washed and sterilised in one operation

The table clearly shows the bacteriological superiority of boiling over ordinary low temperature washing The advantage of boiling over chemical sterilisation—that heat is known to be effective against tubercle bacilli and pseudomonas—is not shown in the table, and we have done no experiments to confirm that this is so under laundry conditions

The greater inflammability of cotton compared with wool must be seriously considered Blankets on a bed are not often exposed to a flame, but a lighted match or cigarette may be accidentally dropped on them This causes no more than local scorching to woollen blankets In the same circumstances the two cotton materials smoulder and sometimes burn, but the spread of the flame is irregular and slow It is difficult to say whether this is a serious objection to their use in hospital, but we are inclined to think it is not Terylene, in these circumstances, is not inflammable The cotton materials can be flame proofed and the treatment would add about 7*s* 6*d* to the cost of each blanket

The generation of static electricity by fabrics sometimes causes explosions, and when new materials are introduced into hospitals this should be borne in mind though it is not generally known that even wool is able to cause sparking Cotton is much less liable to do this but terylene builds up high charges and sparking easily occurs Blankets of this material should not be brought near anæsthetic or other explosive gases

The choice between the available materials for hospital blankets is not easy There are large stocks of woollen blankets and there can be no question of discarding the[illegible] While they remain in use they can be washed regularly by a low-temperature process and should be disinfected by a quaternary ammonium rinse It is our opinion however, that as these stocks are exhausted they should be replaced by boilable materials because the disinfecting process for these is simpler and destroys a wider range of organisms The high cost of terylene and towelling compared with wool is offset by their longer life if regularly washed and sterilised, but it seems unlikely that terylene will be accepted in most hospitals until its liability to cause sparking can be reduced or eliminated Loomstate cotton weave is cheap, durable, and free from static sparking, and seems to be the best choice at present All three materials will have to be used for several years before their costs can be properly compared with each other and with wool , but we thought it would be useful to publish these preliminary results without delay, so that others who wish to do so can make the comparison for themselves

We did not set out to investigate the effect of sterilised blankets on the frequency of wound infection nor even on the bacterial population of the ward We accepted the fact that blankets should be sterilised, and we conducted these trials with the sole object of finding an inexpensive material which could be sterilised easily and effectively Nevertheless, it was natural that we should take more than a casual interest in the incidence of wound infection during the trials Many of the patients with burns were admitted to the wards ten or more days after the accident and infection with *Staphylococcus aureus* and *Streptococcus pyogenes* was often well established by this time It was not possible to separate these patients from others with clean wounds Before our investigations began, infection often spread between patients in adjacent beds and then to those in other parts of the ward, despite the fact that all dressings were done in a room outside the ward We therefore concluded that organisms from contaminated blankets were passing through the patients' dressings and were also infecting the air of the ward During the trial wound infection became less frequent We do not attribute this entirely to the sterilisation of blankets because other methods of dust control and general measures against cross infection had been begun about the same time We think, however, that it may have played a part

Summary

Hospital blankets are reservoirs of pathogenic organisms, unless they are frequently sterilised Ordinary washing does not sterilise them

Woollen blankets deteriorate rapidly if washed and sterilised often

Blankets made from cotton or 'Terylene' can be simultaneously washed and sterilised by boiling without serious damage

---

§ Supplied by Imperial Chemical Industries Ltd Terylene Council, Hookstone Road Harrogate

Blankets of these materials have been tried in regular hospital use, and have been found satisfactory in all respects, except that cotton is rather more inflammable than wool (although not dangerously so) and terylene more easily causes static electrical sparking

We wish to thank the Cotton Board for valuable advice, Imperial Chemical Industries Ltd, William Cunningham & Co Ltd, and John Kershaw & Co Ltd for providing the materials with which these trials were made, and the nursing staffs at Hemlington and Poole Hospitals for their coöperation.

CIGARETTE SMOKING AT SCHOOL

A PARRY JONES
M.B Cardiff, D P H
DEPUTY MEDICAL OFFICER OF HEALTH, CHELTENHAM

THOUGH many schoolmasters can make a shrewd estimate of the prevalence of cigarette smoking in their classes, more definite information is scanty This article records the smoking habits of the pupils at a secondary modern school for boys Nearly all were 11–15 years of age, but a few were 16 Each was questioned in the presence of his fellows and of his class teacher The interviews took place on two consecutive days and all the 307 pupils in attendance were seen

FINDINGS

The boys were asked whether they had ever smoked a cigarette, and (if so) when they first did so Over two-thirds of the 32 11-year olds had already tried smoking, and 38% of all the boys said that they had smoked before entering the school at 11+ One claimed that he had first smoked at 6 years, and several at 7

TABLE I—PROPORTION OF BOYS STATING THAT THEY WERE REGULAR SMOKERS

—	Age						Total
	11	12	13	14	15	16	
No of boys	32	68	75	93	34	5	307
Yes	1	19	19	41	16	1	97
% yes	3	28	25	44	47	20	32

The next question was are you smoking cigarettes regularly now? Of the boys aged 11, only 1 considered himself a regular smoker, but the numbers rose dramatically at 12 and again at 14 (table I) By their own account, no fewer than 32% of the boys in the school were regular smokers

Finally the smokers were asked how many cigarettes they smoked each week. The replies were surprising (table II) One 13-year-old regularly smoked over thirty a week, and two 14 year-olds smoked over forty (A few words with their form-masters confirmed their claims) Few in the younger age-groups smoked more than five cigarettes a week, but the consumption tended to increase with age Certain tobacconists in the town sell cigarettes singly and it was from these sources that many obtained their supplies

TABLE II—NUMBER OF CIGARETTES SMOKED WEEKLY

Amount smoked	Age					
	11	12	13	14	15	16
Under 5	1	16	13	15	8	1
5–9		2	5	13	4	
Over 10		1	1	13	4	
Total	1	19	19	41	16	1

COMMENTS

These replies cannot be verified and the boys may have exaggerated their smoking habits through pride, but an opposite bias may well have been operative in this survey, for smoking is prohibited both during school hours and whilst the pupils are journeying to and from school. The enquiry was conducted on the school premises and the investigator was known to the pupils as a result of his duties with the School Health Service A few boys may, therefore, have repressed details of their smoking habits for fear of authoritarian repercussions

The results of this survey cannot be applied unreservedly to other secondary modern schools, neither can the smoking habits of the survey pupils be regarded as typical for all boys of their age This Secondary Modern School serves a predominantly working-class area, where many of the senior pupils work outside school hours Consequently, there can be no denying that the results of this survey may be abnormally high

At present, no action is being taken to inform the public repeatedly about the possible dangers of cigarette smoking The decision is based, apparently, on the fact that scientific proof of the causation of lung cancer is lacking[1] This may be contested on the grounds that in the past, preventive action has not waited upon complete proof of causation The first public-health measures in this country were instigated on the strength of a demonstrated association between insanitary living conditions and certain infectious diseases The result was that many infectious diseases such as cholera and typhus, had been virtually eliminated before the causal organisms were identified.

Surely, a programme of school lectures on the possible dangers of cigarette-smoking would be sound, and the law forbidding the sale of cigarettes to juveniles (Section 7, Children and Young Persons Act, 1933) should be more strictly enforced It is reputed that the Battle of Waterloo was won on the playing fields of Eton unhappily, the lung cancer statistics of a future Registrar-General are being determined on the playing fields of the modern generation

I am grateful to Dr T O P D Lawson, medical officer of health for Cheltenham, and to the headmaster of the school for their encouragement and advice

UNIVERSITY DEVELOPMENTS

BETWEEN the Exchequer and the universities, finance is measured by quinquennia, and last week the Chancellor announced in Parliament (see p 642), the Treasury grants for 1957–62 These will rise from £30½ million in 1957–58 to £39½ million in 1961–62 The grant for 1952–53 was £20 million, and the increase recognises the difficulties which the universities have faced and are still facing Even so, as Mr Thorneycroft pointed out, the grants take no account of the latest increases in academic salaries[2]

In deciding how much these grants should be, he had before him the interim report[3] of the University Grants Committee for 1952–56 The committee considers that the way in which the universities have met the economic strains of the past years "should strengthen public confidence in their administration" They have had to meet rising costs by curtailing development; but, even so, in 1955–56 their aggregate expenditure exceeded their aggregate income by £326,000

---

[1] *Brit med J* 1956 ii 1246
[2] See *Lancet* March 16 1957, p 583
[3] University Development Cmd 79 H.M. Stationery Office 1957 Pp 26 1s. 3d

At present, parliamentary grants provide 72 7% of the universities' income (compared with 66 5% in 1951–52) The universities disinclination to become entirely dependent on the State, either for maintenance or capital expenditure, fosters their habit of self-help and economy, and is one of the reasons for their decision—reluctant and tardy—to raise their fees to students The increases which start in 1957–58 will bring in additional revenue of £500,000–£600,000 a year

In 1955–56 the universities received £7½ million in "non-recurrent" grants for building and adapting accommodation, and in the last nine years £31¼ million has been spent on university building But their needs have by no means been met This is partly because of rising costs and partly because of the rising number of students On their visits to the universities members of the committee saw at first hand overcrowding in libraries, lecture-rooms, and student refectories They report that "in some universities laboratories are still housed in huts erected for emergency purposes in the 1914–18 war and scientific research is still carried out in ill-lit basements and cupboards"

The number of students enrolled in the universities of Great Britain in 1956 was 88,701—more than ever before The growing number of pupils remaining at school till the age of 17 (twice as many as in 1939) and the increase in university awards from public funds has more than made up for the absence of the ex Service students of the immediate post war years In view of these numbers the improvement in the staff-student ratio—1 7 in 1955–56 compared with 1 8 in 1951–52—is satisfactory, but the committee adds a warning that where additional appointments are due to the needs of research and increased specialisation the "effect on undergraduate teaching is less than might appear"

The distribution of students among the faculties is shifting, science and technology are gaining at the expense of arts and medicine 2441 students began their medical course in October, 1956 (compared with 2700 in 1955, 2674 in 1954, 2614 in 1953), while the total number of medical students was 13,035 (14 7% of all students compared with 23 8% in 1938–39) The committee considers that one of the reasons for the reduced demand for entry to the medical schools is "the continued increase in the numbers on the Medical Register"

Public Health

CONTROL OF AN OUTBREAK OF STAPHYLOCOCCAL INFECTION IN A HOSPITAL

W A GILLESPIE
M A, M D Dubl, M R C P I, D P H
PATHOLOGIST

V G ALDER
B Sc Brist, F I M L T
CHIEF TECHNICIAN

UNITED BRISTOL HOSPITALS

STAPHYLOCOCCAL infections in hospitals are often caused by several prevalent strains of the organism Sometimes, however, a series of infections is caused by a single epidemic strain which seems to be exceptionally virulent We describe here such an outbreak and the measures taken to stop it

All the staphylococci referred to here were coagulase positive They were phage-typed by the method of Williams and Rippon (1952), using the basic set of Colindale phages (Anderson and Williams 1956)

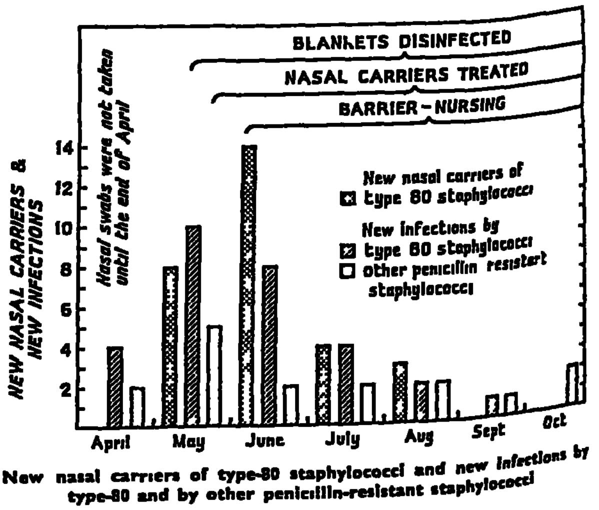
The Infections

In March, 1956, 2 babies were admitted to the Bristol Children's Hospital for treatment of staphylococcal pneumonia and empyema contracted in another hospital, where there had recently been several cases of severe staphylococcal sepsis One of the babies died after three days The other recovered and was discharged seven weeks later Pus from the chest of each yielded *Staphylococcus aureus*, resistant to penicillin, streptomycin, and oxytetracycline, and sensitive to chloramphenicol and erythromycin Both strains had the same phage type, with the basic set of phages at their routine test dilution (R T D) they were lysed by phage 80 only They produced opacity in egg yolk broth (Gillespie and Alder 1952) Similar staphylococci were isolated from the throat and conjunctiva of 1 of the patients Shortly afterwards a nurse developed a large boil on her face, from which a similar staphylococcus was isolated on April 5 She was found to be carrying the same strain in her nose She had worked for three nights in the ward where the 2 babies were

From April 1 until Sept 30 type-80 staphylococci caused twenty nine suppurative lesions in 14 patients and 4 nurses A few of the staphylococci were weakly lysed by the phage 73 at R T D as well as being strongly lysed by phage 80 The staphylococci were otherwise identical with those isolated from the two babies referred to above and probably belonged to the same strain The strain may have been introduced by the 2 babies, but this is uncertain because few staphylococci previously isolated in the hospital had been phage typed A tendency to cause repeated infections in the same person was a feature of the organism, 5 patients had two or more lesions During the same period all the other penicillin resistant staphylococci in the hospital caused only 15 infections, and no person had more than one lesion Most of the type-80 infections took place before the end of June, by which time measures to stop the outbreak were well under way (see figure)

The exceptional virulence of the type 80 strain was shown by its ability to cause most of the infections while being *greatly outnumbered* by other penicillin resistant staphylococci in the noses of nurses and patients, only 38 type 80 cultures were identified among the 174 penicillin-resistant staphylococci isolated from all the nasal swabs taken between April 26 and July 10 (Some nasal carriers were swabbed *more* than once) The virulence of the strain was also shown by its greater tendency to cause furunculosis and subcutaneous abscesses, often with unusually severe inflammation of the surrounding tissue (table I) The strain caused pneumonia and empyema in 2 patients in addition to the 2 admitted with the infection

The type 80 strain appeared to invade noses readily It was isolated from the nasal swabs of 12 of the 23



New nasal carriers of type-80 staphylococci and new infections by type-80 and by other penicillin-resistant staphylococci

TABLE I—INFECTIONS CAUSED BY HOSPITAL STAPHYLOCOCCI BETWEEN APRIL 1 AND SEPT 30

Organism	Primary sepsis of skin and subcutaneous abscesses	Pneumonia and empyema	Infections of wounds and burns
Type 80 strain	19	2	8
All other penicillin resistant staphylococci	4	0	11

For the comparison between the first and third columns χ^2 (corrected for continuity) = 5 75, $P<0\ 02$

patients who in May and early June were found to be carrying penicillin resistant staphylococci Most of these patients had been admitted after April 1 We were unable to determine the importance of nasal spread compared with other routes of spread To have tried to do so would have delayed the measures taken to stop the outbreak Nevertheless it seemed important to treat the nasal carriers of the type 80 strain and to prevent others from becoming carriers

Preventive Measures

Three steps were taken Most of the patients whose lesions or noses contained the type-80 strain were barrier-nursed, nasal carriers were treated, and bed-clothes were disinfected

At first the patients were nursed in their own wards, but after June 6 most of them were kept in one of two wards so that barrier-nursing could be more thoroughly practised The precautions taken in these wards included the use of 'Hibitane' (I C I) hand cream by the nurses who attended to the infected patients, and the application of 'Graneodin' ointment (Squibb) once or twice a day to the nostrils of all patients and nurses who were not carriers Carriers were treated more intensively, as described below

Treatment of Nasal Carriers

A search for nasal carriers was started on April 26 Swabs moistened with saline solution were taken from patients and nurses a ward at a time until the eight wards (114 beds) had been covered This programme was then repeated several times, but swabbing was done more often in the wards which contained carriers or open type 80 staphylococcal lesions than in other wards The resident medical and domestic staff were swabbed twice, but none of them were found to be carriers of the type 80 strain By Sept 26 the wards had been swabbed from five to nine times 1401 nasal swabs had been taken, and 29 carriers, including 7 nurses, had been identified

At first the swabs were plated on nutrient agar Later the medium was made selective for organisms with the antibiotic resistance of the type 80 staphylococci by adding to it streptomycin 5 µg per ml and oxytetracycline 10 µg per ml Six swabs were inoculated, without spreading, on segments of each selective plate This modification greatly simplified the work The positive egg yolk reaction of the type-80 strain was also useful in selecting cultures for phage typing, since most other staphylococci with the same antibiotic resistance-pattern were egg-yolk negative

TABLE II—RESULTS OF TREATMENT OF NASAL CARRIERS OF TYPE 80 STAPHYLOCOCCI WITH GRANEODIN

—	Number treated	Relapsed during treatment	Relapsed within 6 weeks of stopping treatment
Nurses	7	0	2
Patients	15	4*	At least 3 total not known

* 2 patients had septic lesions from which their noses may have been reinfected

Starting at the beginning of April with the nurses and six weeks later with the patients we treated the noses of the type-80 carriers four times a day with graneodin ointment, which contains gramicidin and neomycin The ointment was gently smeared inside the patients' nostrils usually with glass rods The nurses usually applied it to their own noses with their fingers It was intended to treat the patient carriers for at least a week after their swabs became negative, but several left hospital before completing their treatment The swabbing was not repeated often enough to determine how quickly the staphylococci disappeared, but in several cases a negative swab was obtained within a week of starting treatment The type-80 strain persisted or reappeared in the noses of 4 of the 15 patients while graneodin was still being used but disappeared with further treatment, 2 of these patients had septic lesions from which they may have reinfected their noses At least 3 patients relapsed after stopping treatment, but others may have relapsed after leaving hospital

The 7 nurses who were nasal carriers of the type 80 strain gave negative swabs within a week of starting treatment, but most of them continued to use the ointment for two to four weeks more The strain reappeared in the swabs of 2 nurses who had stopped treatment after shorter periods in 1 of them the carrier state was brought to an end by further treatment, the other left the hospital before further treatment could be given

The results of graneodin treatment are summarised in table II The treatment did not irritate the nostrils

Disinfection of Bedding

During the last fortnight of May all patients' garments and bedding were disinfected a ward at a time Subsequently the bedding from contaminated wards was disinfected as the patients left hospital Non-woollen articles were disinfected by laundering at a temperature high enough to kill staphylococci Blankets and other woollen goods were treated with moist formaldehyde vapour in an autoclave chamber A flexible copper tube ($^1/_{16}$ inch bore) was fitted through a gland in the door of a horizontal cylindrical dressings autoclave of capacity 22 c ft The blankets were placed loosely in a wire cage inside the chamber, 18 at a time The jacket was heated by admitting steam to a pressure of 25 lb and then turning it off Steam was not admitted to the chamber A 20 inch vacuum was then created in the chamber by means of the ejector, and 75 ml of formalin (40% formaldehyde), with an additional 400 ml of water, was allowed to flow in slowly through the copper tube, the inner end of which had been placed so that the fluid would fall on the hot jacket lining and not on the blankets After an hour the vapour was removed by creating a vacuum, admitting air, and then creating another vacuum

The formalin treatment did not shrink nor otherwise damage the blankets "Sweep-plate" cultures (Williams, cited by Blowers and Wallace 1955) showed that more than 95% of the bacteria in the blankets were killed Most of the survivors were aerobic sporing bacilli The only disadvantage of the method was the smallness of the load which could be disinfected at a time In subsequent work with an autoclave of 53 c ft capacity loads of 36 blankets have been disinfected satisfactorily

Results

The numbers of type-80 staphylococcal infections and of new nasal carriers fell sharply after June (see figure) 3 of the 7 infections which occurred during the next three months were in patients who had had similar infections previously The single type 80 staphylococcal infection in September was in a nurse who developed a pustule of the skin and a subcutaneous abscess some weeks after leaving the hospital She was known to be a carrier of the type 80 strain

Discussion

Anderson and Williams (1956) emphasise the importance of determining whether a series of staphylococcal infections in a hospital is caused by a single epidemic strain or by several strains If one strain is responsible, its recognition in lesions and in carrier sites is an important step in control For this purpose phage-typing is of first importance, but the antibiotic resistance pattern and other properties of the strain may help to distinguish it from other staphylococci and thus facilitate the selection of cultures for typing The antibiotic resistance may also permit the use of a selective medium for the isolation of the organism, as in the present work

In the control of an epidemic caused by one strain steps should be taken to reduce cross infection in general as well as to eliminate the epidemic strain The disinfection of bed-clothes is an important general measure and may be done by laundering with a quaternary ammonium compound (Blowers and Wallace 1955) or by means of warm formaldehyde vapour in the presence of saturated water vapour With formaldehyde care must be taken to ensure adequate penetration by placing the blankets loosely in the chamber Our method was a hasty improvisation and probably could be improved by using an apparatus such as that supplied by Messrs Manlove Alliott for attachment to hospital autoclaves

Both the barrier-nursing of patients with open sepsis and the treatment of nasal carriers were probably important causes of the elimination of the epidemic strain There can be little doubt of the importance of nasal carriers Hare and Thomas (1956) have shown that nasal carriers can heavily contaminate the environment with staphylococci Gillespie et al (1957) have described an outbreak of neonatal pemphigus caused by a single nasal carrier of an epidemic strain of *Staph aureus* Rountree et al (1956) reported a reduction in the incidence of neonatal infections after staphylococcal carriers among nurses had been treated with 'Neotracin,' an ointment containing bacitracin and neomycin Graneodin has proved to be reasonably effective in treating nasal carriers Like neotracin, it has the advantages that neither of its constituents is often used parenterally and that the presence of two antibiotics reduces the risk that staphylococci will become resistant to either Subsequent experience with children and adults has shown us that persistence of the staphylococcus in a nasal swab taken after a few days' treatment with graneodin usually shows that the ointment is not being correctly used The principal fault is failure to smear it over the skin inside the anterior nares Sometimes, however, it may be difficult to eradicate a staphylococcus from the nose of an infirm or elderly patient, especially if the nostrils contain many hairs Relapse after graneodin treatment, with reappearance of the same strain, does not often happen, provided that the treatment is continued for at least a week after the swab becomes negative The relapse-rate has been lower with nurses than with patients, probably because the nurses usually persisted with the treatment longer than did many of the patients E S Duthie (personal communication) has also had satisfactory results with graneodin

Unusually severe staphylococcal infections caused by phage-type 80 strains were first described in Australia (Rountree and Freeman 1955) and subsequently in this country (Anderson and Williams 1956, E S Duthie, personal communication) Probably, however, exceptional virulence is not a property of all type-80 staphylococci For more than a year we have encountered strains with the same phage pattern but differing in antibiotic sensitivity from our epidemic strain in adult surgical wards and in a maternity hospital, they have not been more virulent than the other staphylococci in the wards

Summary

An outbreak of staphylococcal infections in a children's hospital was caused by an exceptionally virulent strain of *Staph aureus* which had the phage-pattern 80

The antibiotic resistance of the strain permitted the use of a selective medium for its isolation and facilitated its speedy recognition

The outbreak was brought to an end by barrier nursing patients with open sepsis, treating nasal carriers with graneodin ointment, and disinfecting blankets with formaldehyde.

We wish to thank Mr F L Mason and Dr H. M Darlow for advice on the use of formaldehyde, and the matron and nurses of the Bristol Children's Hospital for their efficient cooperation

ADDENDUM

Since this paper was written, we have had two further opportunities of evaluating the treatment of nasal carriers with graneodin The type-80 strain was reintroduced into the Children's Hospital by a child who had been an inpatient during the earlier epidemic It spread to the noses of several patients, but was removed from each, within a few days, by the use of graneodin On the other hand, graneodin failed to remove the staphylococci from about a third of the carriers of several prevalent strains in two male surgical wards, where most of the patients were middle aged or elderly Failure was common with patients whose wounds were already infected

Tetanus after Operation

Inquiries are continuing into the outbreak of tetanus at the North Staffordshire Royal Infirmary, Stoke-on Trent, to which we referred in our annotation last week *5 patients operated on at the infirmary* between Feb 21 and 25 were infected and 2 have died Symptoms appeared in the first case on Feb 26, the incubation periods ranged from five to eight days In 3 cases it was necessary to resort to tracheotomy, curarisation, and positive-pressure respiration The other 2 patients were treated with deep sedation and postural drainage

The theatre suite in which the patients were operated on was closed from Feb 28 and, in a written parliamentary answer, the Minister of Health stated that it will not be brought into use again until any necessary measures have been taken to prevent any risk of further infection All patients operated on between Feb 21 and 26 who were still in hospital were given tetanus antitoxin on March 1 and 2 6 patients had been discharged and their family doctors were advised to give them antitoxin

Psittacosis

In 1954 the director of the public health laboratory in Luton, Dr J H O Walker, arranged with the chest physician, Dr Brian Shaw, for blood to be taken from patients with pneumonia and investigated serologically for influenza, psittacosis, Q fever, &c Dr Shaw has continued the inquiry in association with Dr H D Holt, the present director *During 1955 there were* 11 Luton patients out of 191 (about 1 in 17) whose sera was positive for psittacosis—i e, whose antibody titre was 1/125 or over, or who showed a fourfold rise or greater During 1956 there were 40 patients out of 279 with sera positive to psittacosis—about 1 in 7 Of control sera from 300 patients, mainly from antenatal clinics, 3 were positive to psittacosis (1 in 100) We understand that the proportion of people with budgerigars or other household pets in their homes was not significantly greater in the positive group The full significance of these results is as yet uncertain, and attempts to isolate the virus might be one way of *clarifying the serological findings*

In England Now

A Running Commentary by Peripatetic Correspondents

TYRANNY can flourish in a country that prides itself on its anti-autocratic ways This thought is prompted by my experience of the after-dinner speech—an institution which, I hope, is nowhere more firmly established than in democratic Britain What happened the other evening is a fair example

The dinner began quietly, and then under the influence of *Bombe Tutti Frutti*, my neighbour revealed himself as the elder brother of Smith mi of my school days at Harlborough Smith mi ? Yes, now I remembered ! In the summer of '08 we had a famous adventure—climbing through the dormitory window and going for a midnight bathe It was a long story, and it was hardly launched when the toast master's gavel fell By then the ice had thawed everywhere, and he had to knock thrice to win attention After the loyal toast I viewed my companion through the smoke and started again, but hardly were Smith mi and I through the dormitory window when the gavel fell once more Half an hour later, at the next gap, I reminded my companion of who I was and began yet again—but this time in more subdued tones Indeed I noticed that at every table the diners, formerly relaxed and jocose, were taut and watchful, as if at a funeral where the body might appear at any moment from they knew not where When, soon after 11 30, the last speaker sat down, no buzz of eager talk broke loose I gazed at my companion and remembered that it was Robinson ma who had gone with me Smith mi had been the little stinker who had not blenched at drawing authority's attention to the outing Murmuring something about last trains, I made for the door

On the way home I fell to thinking that we have broken free from the tyranny of the usual bird at these dinners—some now offer a cut off the joint, and the very best a bit of steak followed by cheese Why can't we show the same zest for reform with the speeches, so that the diners can talk together at the time when they most want to ? For speeches five minutes should be the invariable limit Then I remembered that next week I'm going to reply for the guests at the Little Porchester Society's annual dinner My hosts might be hurt if I didn t spin out my remarks for twenty minutes—or perhaps twenty-five But that of course is an exceptional occasion

* * *

" If you call in and see me next Saturday I will have the result of your blood test "

" Well, doctor, there is some doubt whether I can make it, as I am appearing before the quarter sessions this week If I don't perhaps you could send the report on to me They give you good treatment in those places, so I am told Mind you, I have a fifty fifty chance of getting off I have a good lawyer "

On asking what the charge was I was told it was housebreaking Murmuring " Good luck ! " I left to cross to the female side of the clinic When I returned he had gone The technician who had taken his blood announced that after I had left the patient had said, " That's a nice doctor Where does he live ? " The technician added maliciously that he had drawn a map

* * *

The Lancet has always been generous in giving space to the problems of examinations as they affect the young—medical students and nurses—but I don't remember any discussion on similar troubles among the over-fifties Last month on the penultimate day of a ski-ing holiday the instructor took our names carefully, which I assumed was something to do with the ski-school office, and told us to meet behind the church next morning instead of at the nursery-slopes When we got there a group were erecting a banner over a finishing-line and we were told to climb to a distant point where our class was to assemble for the start Here, then, was I, in advanced middle-age faced once again with a trial of skill The more experienced classes came first, rushing down from higher up the mountain I discussed tranquillisers in German with an attractive young matron, comparing ' Slivovitz ' with ' Oblivon,' until I realised that she was Dutch, spoke better English than my German, and had a husband who was a pharmacuetical chemist Numbers on our chests, we waited our turn The starter appeared with a red flag, my number was called and I was off

It was a straight-forward course as these things go Something like a side of a house to start with, then a right turn, a bit of straight for recovery, a left turn and down the lower slopes to the finish where the local press photographer risked his life and camera as we flung ourselves over the line and tried to keep upright That evening at the large hotel they distributed the prizes To my great astonishment I was second of the men in my class and received an impressive certificate I was stupidly almost as thrilled as when I passed my membership—thirty years before The family think, in view of my sympathetic interest in child psychiatry, that I ought to put Dip Ski after my name but I doubt if the G M C would register it

* * *

Let not your Scot be too troubled or afraid about those twelve medically qualified Sassenachs to be found, at a cost of 7 guineas, in the Registrar General's *Occupation Tables 1951* If he will look at the corresponding Scottish volume—a mere £6 or so—he will find one doctor aged 15, one aged 16, one aged 17, and three more also under 20 Considering the disparity of population, that's pretty good going for Scotland

* * *

The steps at the entrance to the Wallace Collection are a little high, so I arrived with Janet, aged 18 months, sitting on my hip I was greeted with " I am afraid you can't bring the baby in here, Sir ! " We retired in confusion and outside the door discussed how else we could spend a cold Sunday afternoon when we had come so far Janet was now standing independently and this sight must have softened the door-keeper, who poked his head out and asked, " Can the little girl walk ? If she can walk in by herself that lets me out all right " He was assured that she could walk, and so I led her to the turnstile where she was so fascinated by the polished brass gate that she insisted on pushing it around twice before she could be persuaded to enter the realms of art There she showed a real but highly selective appreciation of all that was offered A pointing finger and barely breathed " Pretty ! " indicated her fullest approval So far we had progressed hand in hand, but I carried her (fortunately unobserved) up the main staircase to where Venice lies There we lingered rather and the small legs wearied, but I no sooner had them straddling my hip again than I was warned by a gruff, " The little girl must walk or she must go " " But she is just tired, can't I carry her for a rest ? " " If she doesn't walk she can't stay " So out we had to walk, Janet casting reproachful looks at this human who had not given her the accustomed great welcome We went on to the Tate where, to play safe, we walked Janet (with assistance) up all those steps and put her in her own quadrant of the great circular door She immediately discovered the joys of walking along the lines in the marble floor and then scrambling along the seats in the galleries But all here was friendly The attendants played peep-bo around the seats and waved bye-bye down the galleries, so that in no time I was bold enough to carry her and no-one objected All this was most circumspectly done and I hope that no trustee of the Tate who may read this will fear that our progress was a riot and resolve to ban babies from tasting art in comfort and with transport according to their needs, for there is no doubt of the delight they gather from their chosen works

* * *

Our statesmen's faith in the eternal wisdom of industrialists is once more evident in the constitution of the Royal Commission on medical remuneration Would it not be a happy reciprocal gesture to appoint a Royal Commission of doctors to investigate any current disturbance in industry ?

Letters to the Editor

GOVERNMENT AND PROFESSION

SIR,—Your leader of March 2 on the remuneration claim sets forth first of all those facts that must excite a deep disquiet in all who care for the future of the profession and then appears summarily to condemn the only means of effective action

I do believe, however, that there are compelling arguments against using the threat of mass withdrawal from the service as a weapon of coercion against the Government Firstly, those who express support for such a course include an uncertain number who hope that words and posturings may be enough and that action may never be called for, to negotiate from this position is to negotiate from weakness In the second place, not only are these tactics the least likely to be effective—and I have no doubt that the Prime Minister has the advantage of an expert assessment of the strength of such opposition from sources within the Cabinet—to attempt them is to presume that it would be sufficient if the aims of the threat were achieved But the lesson of the past ten years is that no Government guarantee is so explicit and so binding as to be able to withstand considerations of expediency, and even if the claim were now to be conceded in full the future would be packed with uncertainties, the one sure thing, indeed, is that in one or two or three years the report of a Royal Commission, whose composition and terms of reference must arouse only foreboding, will open up the sores once more

In such circumstances, all who have the long-term interests of the profession—and of their patients—at heart can hardly be satisfied until it is delivered from any service financed and administered by Government It follows that, whatever the Government may now concede, all who wish to do so must be given the chance to withdraw from the service

You would surely agree that those who may desire to do this are entitled to send in their resignations in an organised manner not in order to coerce, but in order to ensure that none may be denied this opportunity for fear of acting alone, and to afford themselves mutual help and support in the difficult times that may lie ahead for some

Rugeley Staffs P M HIGGINS

SIR,—Mr T B Layton's letter last week is most timely when the medical profession, in its more or less recent union with Government, is beginning to feel the effects of this uneasy marriage How far it should follow the examples set by others in similar circumstances is a matter for no hasty decisions

Mr Layton writes that trade unionism has become the accepted means—presumably for discussion—for those who work with their hands While I am not very clear about his distinctions between working with hands or mind, I do hope with him that the medical profession will set an example and maintain its dignity in their grievance, if this is real, rather than follow some of the worst traits of trade unionism This, I feel sure, is the immediate aim and that full work will be continued if under different conditions, while adjustments are sought, for, or so it seems, a primary principle is at stake—the freedom to work as well as to strike

If this principle is not always upheld in full then an authority may emerge in this country besides which medieval feudalism will lapse into a pale or near invisible shadow

London W 1 F D SAYER

SIR,—Instead of concentrating exclusively on direct financial issues in the present dispute with the Government, would it not be more fitting that the medical profession should take advantage of the relative fluidity of the situation to attempt instead to achieve two fundamental reforms in the health service

(1) The granting of the right to National Health Service prescriptions to patients who consult their doctor outside the service

(2) The limitation of registrar appointments to a small number of specially selected hospitals, and their replacement in the others by consultants

The first step would free general practice from the bonds of being almost exclusively a Government monopoly, and by encouraging smaller lists improve its quality as well as provide openings for the large number of young doctors seeking such openings While the latter would immediately and permanently solve the registrar problem, a problem which unless soon solved threatens the foundations of the quality of the hospital services

London, W 1 DAVID H PATEY

SIR,—An extra payment at least to general practitioners, *without prejudicing their claim and readjustment*, could be made in April simply by releasing now the payment for expenses due in January, 1958 It would be a gesture of goodwill instead of the harsh and cynical attitude of disregard Already the impression is gaining ground that the Government is always ready to give the aspirations, advice, and interests of the managers and executives of the industrial, financial and trade organisations every consideration, while the scientists, the professional men, and the workers have been allotted the rôle of dumb, faithful, and obedient servants

Epping H KORTE

URINARY STEROID PATTERNS IN BREAST CANCER

SIR,—In your leading article of March 9, on Hypophysectomy for Cancer, you suggest that a preoperative urinary analysis of the ratio of 11 deoxy, 17 ketosteroids to 11-oxy, 17 ketosteroids may prove of value in predicting the response to endocrine ablative surgery in patients with advanced cancer of the breast

Unpublished results obtained in this department employing delicate methods of analysis, based on the work of Dobriner,[1] and Edwards et al,[2] indicate no obvious correlation between preoperative steroid patterns and response to surgery

Case no	11 deoxy, 17 ks (mg per 24 hr)	11 oxy 17 ks (mg per 24 hr)	Ratio	Treatment	Response
1	1 35	0 92	1 4	Pituitary implantation and adrenalectomy	−
2	1 13	0 91	1 2	Pituitary implantation	−
3	1 29	1 22	1 5	Pituitary implantation	−
4	1 39	1 15	1 2	Pituitary implantation	+
5	2 63	1 01	2 6	Adrenalectomy	+
6	2 85	0 98	2 9	Pituitary implantation and adrenalectomy	−
7	5 48	1 62	3 4	Ovariectomy	−
8	1 20	1 33	0 9	Ovariectomy	

This in no way reflects upon the suggestion of Dr Merivale and his colleagues (March 9) that a considerably altered hormonal environment (i e, a greatly altered steroid ratio) is necessary for response On the contrary our work gives some support to this idea, since, in a few cases where clinical response was lacking, the steroid ratio, although initially high, was to a large extent unchanged following treatment

[2] Edwards R W H Kellie A E, Wade, A P *Mem*
Endocrinol 1953 2 53

The failure of a patient with a high initial ratio to respond to treatment may be due, in part at least, to a failure of the surgery to change it sufficiently Such a state of affairs would not be predicted on the basis of a preoperative urinary analysis alone

PENICILLIN IN THE TREATMENT OF LACTATIONAL BREAST ABSCESS

SIR,—Mr De Jode, in his article last week, places insufficient emphasis on the advantages of rest for this condition, and continuation of breast-feeding At the first sign of inflammation the patient should be put to bed flat, and when the infant is fed the patient should turn to one or other side still remaining flat Antibiotics will do the rest Of course, in hospital practice one may be faced with a full-blown abscess for which the knife must be used, the conservative treatment must be started early For recurrence of inflammation rest and antibiotics are again indicated

Longtown Cumberland

ROBERT RUTHERFORD

LONG-TERM EFFECT OF DRIED THYROID ON SERUM-LIPOPROTEIN AND SERUM-CHOLESTEROL LEVELS

SIR,—Strisower et al (Jan 19, p 120) report their investigation into the effect of dried thyroid on serum-lipoprotein and serum cholesterol levels This involved the administration of what you described in your leader in the same issue as a "strenuous course" of dried thyroid over 105 weeks to 60 schizophrenic patients in a Californian State mental hospital, the patients then being the subject of various physiological and chemical investigations The authors imply that the only criterion used in selecting the group was chronicity of the mental illness

This use as guineapigs of chronic psychotic patients, who are not able to give or withhold valid permission for experiments in physiological research of this type, must be as repugnant to many of your readers as it is to me It is certainly not in the tradition of the Scottish mental hospital service

Hawkhead Hospital
Glasgow, S W 3

JAMES MILNE

SIR,—I read with great interest the article by Mr Strisower and his colleagues

Though I admire the paper from a scientific point of view, I cannot agree with the methods from the medical-ethical point of view I think that the first thing to be fulfilled in medical experiments is the free-will of the individual to coöperate in the experiment, and I suppose that we cannot expect a free decision from a mentally ill person such as a schizophrenic Therefore I must object to this sort of experiment

Amsterdam

W P J VILTOR

*** These letters have been shown to Mr Strisower and Dr Gofman, who reply as follows "We have been engaged for several years, together with our psychiatric colleagues, in an evaluation of several metabolic and biochemical facets of the problem of schizophrenic and other mental diseases The interest on the part of many investigators about possible thyroidal relationships to schizophrenia is well known Indeed you commented on the reported tolerance of schizophrenics to thyroid in your recent editorial Surely Dr Milne would not be critical of biochemical and metabolic studies directed toward the understanding of the problem of schizophrenia"—ED L

THE B C G LESION IN SARCOIDOSIS

SIR,—I was interested in Dr Borrie's letter (Feb 23), referring to the excellent article (Jan 26) by Dr Forgacs and his colleagues Dr Borrie says "10% of normal individuals who are tuberculin-negative do not become tuberculin-positive after B C G vaccination, and I suggested at the time that this particular constitutional peculiarity may have some bearing on the future development of sarcoidosis"

In the Oxford Regional Hospital Board area, 99 6% of 7371 persons of all ages converted to positive after primary B C G vaccination My own figures for 1951–56 inclusive are 100% in hospital adult staff

I have seen a possible case of sarcoidosis developing in a person who had had B C G vaccination in November, 1951

He was Mantoux-positive to 100 T U two months later (14 mm induration) He had annual chest X rays as a bacteriological laboratory worker In July, 1953, the routine X ray showed bilateral enlarged hilar shadows consonant with sarcoidosis The Mantoux test with 10 and 100 T U was reported as negative Judged by X-rays the lesions had regressed considerably by September, 1953, and the X ray was normal by December, 1953 In January this year the X ray films were still normal, and he had a positive Mantoux test to 10 T U (15 mm) He had no symptoms in 1953 in spite of the X ray appearances, and no overt evidence of tuberculous infection at any time

Had I seen this man in July, 1953, I should have tried to ascertain whether his serum, when mixed with tuberculin in varying dilutions, would inhibit a positive reaction in those known to have one (as a result of either B C G vaccination or natural infection) using control sites as well Had this been done the data might have been of interest I understand from Dr K Neville Irvine that tuberculin testing of patients with sarcoidosis in Sweden has demonstrated the presence of a factor inhibiting tuberculin reactions, and that negative reactors have become positive after recovery from sarcoidosis, though they had been converted to tuberculin-positive by B C G vaccination previously

Patients with sarcoidosis, besides those of Dr Forgacs and his colleagues, remain tuberculin-positive in the apparently active phase of the disease, thus the inhibitory factor is by no means universal It could be that those with apparent sarcoidosis who have a negative tuberculin reaction, and fail to convert after B C G vaccination, have a disease with a different ætiology from that in the more usual cases, but at present this view can only be speculative

Case 9 of Dr Forgacs and his colleagues is damaging to this speculation, since there were skin lesions and the axillary nodes were enlarged, together with the inaccessible intrathoracic charges indicative of sarcoidosis This woman was positive to 0 1 mg (10 T U) initially, and negative to 1 mg six weeks after B C G vaccination

In short, Mantoux reactions in apparent cases of sarcoidosis can be contradictory and confusing

Royal Berkshire Hospital
Reading

GEORGE A JACKSON

SIR,—In his letter Dr Borrie says that "About 10% of normal individuals who are tuberculin negative do not become tuberculin-positive after B C G vaccination " In Lewis, among 3000 vaccinated by the intradermal route there were only 3 who failed to convert these 3000 were done between 1949 and 1953 (spring) Since 1953 another 2000 have had B C G by multiple puncture technique, and here conversion was the rule, although in the early attempts the reactions were not all one would have wished This partial failure was due to the fact that vaccine of suitable B C G content could not be obtained Now, I may say that with Glaxo freeze dried B C G, of 25 mg per ml concentration for percutaneous use, the results are exceptionally good and consistent This vaccine is issued only for experimental purposes

FUNCTIONAL SIGNIFICANCE OF PITUITARY BASOPHILISM

SIR,—Lately several workers have sought to connect the cytomorphological changes, due to various influences, of the adenohypophysis with the production of the trophic hormones Thornton [1] has stated that cortisone treatment is followed by increase in the basophil cells of the adenohypophysis *At first sight it might seem* reasonable to ascribe this change *to inhibition of corti*cotrophin (A C T H) secretion by cortisone Purves [2] and Crooke,[3] however, expressed the opinion that the increase of basophil cells under such circumstances is connected, not with the decreased secretion of corticotrophin, but with the increased production of follicle stimulating hormone (F S H)

Our own studies,[4–6] published in 1954 and 1955, fully accord with this view We demonstrated that the changes in numbers of the basophil cells of the adenohypophysis are due, not to the intensity of corticotrophin secretion, but to the quantity of corticosteroids present in the tissues Increase of basophil cells can be seen in non-specific stresses or after cortisone intake (i e, with an augmented peripheral level of corticosteroids), whereas after adrenalectomy (when corticosteroids are practically absent in the tissues, and the production of corticotrophin on the other hand is intensive) basophil cells decrease

The numbers of basophil cells in any experimental intervention (stress, adrenalectomy, cortisone intake, &c) change in parallel with the quantity of P A S-positive cells And since only the so called glycoproteid hormones (gonadotrophin, thyrotrophin) contain groups oxidisable to aldehyde by periodic acid, it seems fairly certain that the *change in the number of basophil cells* is connected, *not with the production of corticotrophin*, but with that of glycoproteid hormones

That this hypothesis of ours is correct has been supported by parallel quantitative cytomorphological analysis of the adenohypophysis *as well as biological* titration of its gonadotrophin content We have demonstrated that where the basophil cells are increased the F S H content of the hypophyseal extracts is enhanced Further we have found that this increase caused by stress (endogenous corticoids) can be fully avoided by folliculin inhibiting the secretion of F S H; but at the same time the secretion of corticotrophin remains intensive In our current experiments we are trying to inhibit the effect of cortisone (exogenous corticoid) in enhancing the basophil cells by administering œstrogens

In summary, our studies suggest that the cytomorphological picture of the adenohypophysis can be influenced by the corticosteroids Where these are increased, from either endogenous or exogenous sources, basophil hyperplasia results This morphological change is unconnected with the extent of corticotrophin secretion but is connected with the intensity of gonadotrophic hormone production

MUNCHAUSEN'S SYNDROME

SIR,—We wish to thank Dr Heathfield for his timely letter (March 9)

The patient he described presented at midnight last night with the same history of headaches, drowsiness, and deteriorating vision, but on this occasion she did not complain of vomiting On examination the signs were as described by Dr Heathfield On being confronted with extracts from the letter, she denied having visited any of the hospitals mentioned, and attributed her abdominal scars, at first, to a hysterectomy She eventually stated that they were, in fact the result of tuberculous peritonitis *Her alleged occupation* on this occasion was that of porteress

It must be rare for a case of Munchausen's syndrome to be so quickly identified after description in your columns Dr Heathfield's letter has saved much time and expense in pursuing profitless investigations

St. Thomas's Hospital
London, S E 1

R D G PEACHEY

RHEUMATOID ARTHRITIS WITH CHRONIC LEG ULCERATION

SIR,—We were interested to read the article by Dr Allison and Dr Bettley (Feb 9) in which they presented six cases of skin ulcers, emphasising that we have overlooked the possibility of disseminated lupus erythematosus

We have reviewed our twelve published cases of skin ulceration,[1] five of them being at present under hospital care Besides these, we have found five more cases

The follow up time after the diagnosis of ulceration is now from four months to five years All these patients are still alive Except in one case, all show a classical picture of rheumatoid arthritis with typical X-ray changes According to the American Rheumatism Association's classification there were 2 cases in stage II, 9 in stage III, and 5 in stage IV In one case *mentioned above* the diagnosis has not yet been fixed, but polyarteritis nodosa has been suggested

Three of these patients have sometimes had a slight rash *in connection with gold therapy*, but have shown no other symptoms of drug intolerance No other cutaneous manifestations of disseminated lupus erythematosus have been observed in these cases One patient had pleural adhesions Slight tachycardia was present in one case In two cases both systolic and diastolic murmurs were observed Systolic blood pressure was slightly increased in three cases (190–175 mm. Hg) Proteinuria was present in one case (amyloidosis) and a trace of protein was present in the urine in another case These patients had occasional cylindruria L E cells were sought in only five cases, *the results being negative* The anti streptolysin titre was elevated in two cases Slight anæmia was present in all cases The erythrocyte sedimentation rate was increased in each case (values from 11 to 134 mm, Westergren) In *no* case was there hyperpyrexia

---

1 *Acta rheum. scand* 1955, 1 113

In no case was leucopenia found, the lowest value, occasionally found in one case, was 4300 per c mm The highest value was 12,800 per c mm In two cases transitory eosinophilia was found (11 and 27%)

Biopsy of skin and muscle, performed in nine cases, did not reveal definite changes of disseminated lupus erythematosus

Thus, except in one case of possible polyarteritis nodosa, these patients with skin ulceration show a typical picture of rheumatoid arthritis, with no evidence of disseminated lupus erythematosus Further, it is interesting that Allison and Bettley's cases 4 and 5 did not show evidence of disseminated lupus erythematosus, and that in other cases this diagnosis seems to have been based only on the positive L E cell phenomenon and drug eruptions The specificity of the L E cell phenomenon is disputed Nevertheless we have seen in our clinic two patients with definite disseminated lupus erythematosus and multiple ulcers

EPIDERMOID CHOLESTEATOMA AND CHOLESTEROL GRANULOMA OF THE EAR

SIR,—In your interesting leading article on Keratinous Cysts in the C N S (Feb 16) you refer briefly to the pathogenesis of the so called cholesteatoma of the ear

There appears to be no general agreement on the pathogenesis of this structure often complicating chronic otitis media In particular the origin, character, and rôle of its epithelial lining and the rôle of cholesterol in the formation of cholesteatoma have mystified many workers and led to some confusion

There are, in my opinion, two pathological entities to be considered, exhibiting distinct histopathological features the epidermoid cholesteatoma, an epithelial product, and the cholesterol granuloma, the result of the deposition of cholesterol crystals in the infected tissues of the middle ear

Epidermoid Cholesteatoma

The true epidermoid cholesteatoma is a cyst whose wall is lined by keratinising stratified squamous epithelium with its keratinised layers, the surface layers of the epidermis innermost (fig 1) The keratinised layers are being shed in ever increasing numbers into the cavity of the cyst and, usually, with a generous admixture of pus form its contents

It cannot be emphasised too strongly that the cholesteatoma is an epithelial structure produced by keratinising stratified epithelium It is the origin of this epithelium that has remained obscure, and several hypotheses have been advanced The most important are

(1) *Direct extension of epidermis from the external auditory canal as a result of chronic otitis media with perforation of the tympanic membrane*

Experimental evidence[1] has shown how stratified keratinising squamous epithelium may extend from the external auditory meatus or from the tympanic membrane into the experimentally infected middle ear, forming a continuous lining of the bulla of the guineapig In sections of material removed at operations on the human mastoid process, similar findings have been made in many cases of cholesteatoma[2] Moreover, the ingrowing stratified squamous epithelium could be clearly seen undermining the mucosa of the human middle ear, leaving its normal epithelial lining apparently intact

(2) *Metaplasia of existing normal epithelium to a stratified squamous epithelium, also the result of chronic infection*

True squamous metaplasia—that is, the *replacement* of cuboidal or columnar epithelium by stratified squamous epithelium—cannot be entirely ruled out, but is probably uncommon

(3) *Activated cell rests, as is the case with primary intracranial cholesteatoma*

This mode of origin cannot be doubted, but it is a rare cause of aural cholesteatoma

Both human and experimental evidence favours Haberman's original hypothesis that the matrix of a true epidermoid cholesteatoma is formed through the extension of stratified (keratinising) squamous epithelium into the middle ear from the external auditory meatus or from the tympanic membrane

Whether a good or a bad one, the ambiguous term cholesteatoma cannot be easily replaced, but it should be amended by the addition of the attribute "epidermoid"

Cholesterol Granuloma

The cholesterol granuloma differs fundamentally from the epidermoid cholesteatoma It is a granulomatous structure formed by large numbers of cholesterol crystals (clear cleft like spaces in sections) surrounded by foreign-body giant cells and embedded in fibrous granulation tissue (fig 2)

Cholesterol crystals are often present in sections of aural polypi, bone chips, and granulations removed from the infected mastoid process, deposited at the site of hæmorrhage or suppuration

---

1 Friedmann I *J Laryng* 1955 69 588
2 Friedmann I *J clin Path* 1956 9 229

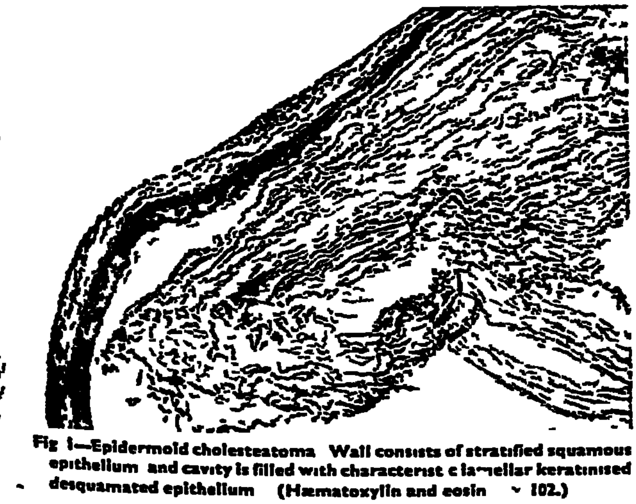

Fig 1—Epidermoid cholesteatoma Wall consists of stratified squamous epithelium and cavity is filled with characteristic lamellar keratinised desquamated epithelium (Hæmatoxylin and eosin × 102.)

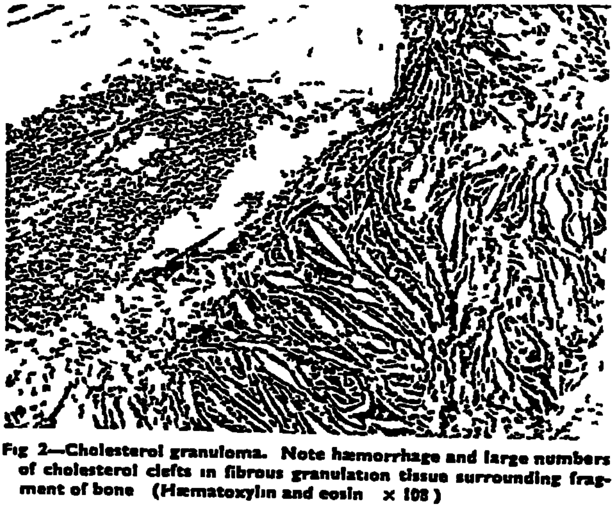

Fig 2—Cholesterol granuloma. Note hæmorrhage and large numbers of cholesterol clefts in fibrous granulation tissue surrounding fragment of bone (Hæmatoxylin and eosin × 108)

no ill effect has been observed, and the hair is left in good condition, with no sign or stigma of treatment. The use of an attractive shampoo overcomes the reluctance of the adolescent and the mother. A first-class shampoo is necessary so that all members of the family will not only tolerate the remedy, but like it and want it.

There is great need for industrial areas, irrespective of local-government boundaries, to attack the problem of infestation together and at the same time. I have tried many insecticides during the past twenty years, and the new lorexane no. 3 appears to be the best remedy.

Acknowledgment is warmly made to those who did all the work: the Salford public-health nursing service (superintendent health visitor, Miss B. M. Langton), and I.C.I. Pharmaceuticals Division for supplies of 'Lorexane' no. 3 shampoo.

Public Health Department,
Salford

J. L. BURN

DYSENTERY DURING ADMINISTRATION OF ANTIBIOTICS

SIR,—The use of antibiotics is usually followed by the appearance of a new microbial flora in the intestine, and when the host is debilitated the new micro-organisms may give rise to a secondary disease—e.g., candidiasis or staphylococcal enterocolitis. Recently we have seen a case of dysentery apparently caused by *Proteus morgani* which arose during administration of tetracycline and penicillin after an operation on the intestine.

A man, aged 30, had for several years had pain in his right lower abdomen. A diagnosis of mobile cæcum was made. At operation, severe chronic inflammation of the cæcum and ascending colon were found. The ileocæcal region, cæcum, and ascending colon were resected and an ileocolostomy was created. Since abdominal distension and high fever continued after the operation, food and water were not given orally for a week; blood and Ringer's solution were infused and vitamins injected; tetracycline 500 mg. daily was administered intravenously with 500 ml. of 5% glucose solution, and penicillin 300,000 units daily was given intramuscularly.

On the 7th day after operation, the patient had severe dysenteric symptoms. From the fæces bacteria of the proteus group were isolated in almost pure culture; they were identified as *Proteus morgani* biologically and serologically. Among the biological properties of the organism was a marked activity of histidine decarboxylase, but the significance of the active production of histamine in this case was not known. The organism was highly resistant to penicillin, erythromycin, tetracycline, chlortetracycline, oxytetracycline, and streptomycin, and only moderately sensitive to chloramphenicol. After oral administration of chloramphenicol 1 g. daily for 3 days, the dysenteric symptoms abated, the fæces became normal, and the organism disappeared from the fæces.

Proteus morgani seems to be mainly commensal but potentially pathogenic.[1 2] It has been cultured from the fæces in sporadic dysentery, enteritis, and diarrhœa, but its pathogenicity is doubtful. Under suitable conditions it seems able to multiply in the intestine, but it can hardly be ranked with the organisms of the shigella group.

In our patient, active growth of *Proteus morgani* in the intestine, resulting from the depression of the normal intestinal microbial flora, may have caused dysenteric lesions—at a time when he was undernourished after the operation on the intestine. In most reported cases, staphylococcal enterocolitis has followed nutritional deficiencies or severe cachectic states. We must therefore pay much more attention to the nutritional state of patients when antimicrobial therapy is being given.

UNMARRIED PARENTHOOD

SIR,—This letter is intended to be an olive-branch. Both Dr. Tuthill and Miss Steel want to see more and more happy marriages, with more and more children growing up in confidence and security because the sexual life of their parents is harmonious and free from morbid associations of guilt. It is a little hard of Miss Steel to call the notions which seem to underlie the letter from Dr. Tuthill, who after all is only out to help those couples whose sex life has gone adrift (often because they have been indoctrinated with "guilt"), "very barbaric and sub-human." To call sex an appetite does not seem to be contradicted by experience, nor indeed by the outspoken phrases of the Book of Common Prayer. Are there not perhaps some couples who are such idealists with regard to sex that they are permanently disappointed, and permanently feeling guilty? While no-one wants children to be born of illegitimate parents there are other kinds of sexual tragedies—e.g., the conscientious couple, both brought up to regard sex as strictly "sacred," who are never free from scruple and inhibition with each other. If things go seriously adrift, such couples need help from outside, and it is possible that the only person who can help them is one who can persuade them to be less solemn and idealistic, more playful and lusty, in their sexual life. We all want to help and to be helped, and I feel we must not get too hot under the collar over the unorthodox opinions and methods of some of the helpers.

EDWARD MANSFIELD

REFLECTIONS ON CIRCULATORY CONTROL

SIR,—Dr. Cecil Gray suggests (Feb. 23) that "hypotension should be reserved for those cases in which it is clearly imperative because of the nature of the surgery; this would limit it to neurosurgical and perhaps some otolaryngological and plastic operations. . . ." Yet there are probably more contra-indications to hypotension in cerebral disorders than in those elsewhere in the body.

For example, Brown[1] pointed out the danger of using hypotension and surgical retraction in the acute phase of *subarachnoid hæmorrhage*, with its concurrent arterial spasm in the vicinity of the aneurysm. He also mentioned the danger of using hypotension in the presence of stretch or distension of major vessels from tumour or other causes. Brown[2] has since pointed out the importance of preventing a fall of blood pressure in seriously ill patients with spasm of the anterior basal perforating arteries.

Access within the skull is considerably aided by good anæsthesia with *attention to* posture, venous drainage from the head and neck, adequate respiratory exchange, the substitution of barbiturate drugs for opiates in premedication, and the use of aids such as ventricular or spinal drainage of cerebrospinal fluid during operation and intravenous infusion of hypertonic salt solution if required. Certainly by these methods operating conditions can be as satisfactory as when hypotension and hypothermia are used. Mortality and morbidity rates, however, are definitely lower, and the patient recovers consciousness more rapidly.

Where major cerebral vessels are not involved by spasm or are not stretched by tumours or other causes, hypotension may be of considerable value. For example, I would regard hypotension as an invaluable aid to the surgical removal of a cerebral arteriovenous *malformation* contributing materially to the excellent surgical results in this condition.

Department of Surgical Neurology,
Royal Infirmary, Edinburgh.

Parliament

Prison Reform

WHEN the public purse is thin it is natural to put the claims of the widow, the sick, and the aged before those of the prisoner But it may not always be wise The public purse is rarely fat, and it is never the prisoner's turn Today shortage of staff, overcrowding, and sanitary squalor are hindering our prisons in their work for the community Members on both sides of the House last week welcomed Mr R A BUTLER's first speech as Home Secretary on this subject, because it rejected what was described as this "last of the queue approach"

Under the drab headings of the Supplementary Estimate, which he was formally introducing, Mr Butler managed adroitly to review the present difficulties of the prison service and put forward his ideas for a better future Accurate knowledge was an indispensable tool of administration, and he admitted that since taking office two months ago he had been shocked to find that in the last nine years the Home Office had spent only about £12,000 on research Some useful work had of course been done, particularly on borstal and approved-school training, probation, and detention-centre treatment, but in his opinion we needed fuller and more accurate information, especially on imprisonment itself We must use the tools which science and sociology had put into our hands to supplement the knowledge gained from experience, and he therefore proposed to give research first priority

OVERCROWDING AND UNDERSTAFFING

He selected as the most urgent problems of prison administration overcrowding and understaffing The best measure of the first perhaps was the number of men who had to sleep three in a cell A year ago this was 2500, now it was little more than 2000 despite an unhappy rise in the prison population from 20,500 to 21,600 *Last year the Prison Commissioners took over another* open prison, making 13 in all He thought it unlikely that this form of relief to accommodation could be taken much further without undue risk to a valuable method We must therefore look for help from the building programme which was now under way

Early next year a prison for 300 men near Hull would be ready for use A similar prison in Lancashire had been started, and work would begin this summer on a psychiatric institution—the East Hubert Institution A small borstal for girls would open later this year, and work on a second would start early next year A site for a borstal for boys had been acquired, and planning clearance was being sought for a second When all these buildings were in use—at least in five years' time—they would provide 1500 more places

Another way of coping with overcrowding was by reducing the inflow of prisoners The Advisory Council on the Treatment of Offenders was considering suggestions for reducing the number of short sentences Though a reduction in these would be welcome the main increase in the prison population was probably due to an increase in the length of sentences passed by the higher courts This was of course a matter for the judiciary, but the Home Office should be able to offer the judges information, based on systematic research, about the results of various forms of treatment, and fuller information about offenders before sentence In his view the most important means of obtaining an expert diagnosis of a prisoner's history and personality was the remand centre Not only would these centres keep young people out of prison but they would provide a focus for research into juvenile delinquency He would like to have an entirely separate centre for adults which would use the same specialised staff

Coming to his other big problem Mr Butler said that 1000 more officers were needed before the local prisons could turn over to a shift system which would give the prisoners a full working day Even on the present shift system the staffs were still below establishment It was important to attract and retain the right kind of men and women, and he and the Secretary of State for Scotland had decided to set up a departmental committee to review pay and conditions of service Meanwhile an immediate increase of pay would shortly be raised before the arbitration tribunal

But material conditions were not the only things that made a job attractive, and he wanted every officer in the service to feel that this was a real vocation To this end consultative committees were being set up and staff refresher courses increased Good human relations between staff and prisoners were also important, and Mr Butler described a successful experiment at Norwich prison

Every man on arrival was assigned to a small group under the particular care of two officers whose duties were arranged so that one or other of them was always about The prisoners knew that there were these officers to whom they should look for help and advice The officers were encouraged to get to know their own group, both as a group and as individuals *and to be ready to make reports on them if necessary* All convicted prisoners, except in special circumstances, were allowed to be in association outside the cells from unlocking in the morning until 7 30 P M Apart from other advantages the time saved to the staff on locking and unlocking, together with some adjustments of their timetable, had made possible for the prisoners a working day of over six hours instead of five

It was hoped soon to extend these methods to some of the smaller local prisons

RESPONSIBILITY AND RESTITUTION

Turning to the question of prisoners' earnings, Mr Butler announced that these were to be raised Under the new arrangement all prisoners would start with a minimum of 1*s* 8*d* a week He readily admitted that this did not sound impressive But more important than decisions about the exact rates to be paid was, he suggested, a reconsideration of the purpose behind the whole scheme The present scheme stimulated industry, but should we not look further. What of the prisoner's self-respect? What of helping him to realise his family and social responsibilities? These were among the declared objects of the treatment and training of prisoners Might they not be furthered by a wider and more imaginative view of the possibilities of earnings as an instrument of training? It might be possible, for example, to devise a scheme which would permit a prisoner to save to help himself and his family on discharge Or, taking an even wider view, to give prisoners a rate comparable with a normal industrial wage, out of which they would pay for their keep in prison, maintain their families, meet their social insurance and other obligations, save towards discharge, and, possibly, pay compensation to their victims

Surely these ideas began to lead us away from the simple conception of punishment, which, over many centuries, had occupied too dominating a position in our penal philosophy? Might it not be that something of value was lost when the relation between the offender and his victim was thought to be one which simple punishment could satisfy, so long as it was left to the State to carry out that obligation of punishment? Was there not also some ethical value in the older conceptions, because they were the older conceptions, of restitution and compensation? "I believe," he ended, "that we might one day come to think of our prisons not as places of punishment—though that they must be since deprivation of liberty must always be a punishment—not only as places where offenders are trained to be better men and better citizens, which is what they seek, however imperfectly, to be now, but also as places where an offender could work out his own or her own personal redemption by paying his or her debt not only to the society whose order he has disturbed, but to the fellow members of that society whom he has wronged"

University Grants for 1957–62

On March 14 the CHANCELLOR OF THE EXCHEQUER, in announcing the recurrent grants which the Exchequer proposes to make to the universities during the next quinquennium, made the following statement

The amount of annual grant to be made available for allocation by the University Grants Committee among the universities towards their recurrent expenditure is normally settled for periods of five years at a time, and I propose to follow this practice The present settlement expires next

July, and I have been considering recommendations made to me by that committee for grants for the ensuing five years

During the five years which are now ending, rising prices and wages have affected every branch of university expenditure, and though additional grants were made available to finance the review of academic salaries which took place in 1954, universities have had to meet other increases in costs without any other assistance I am satisfied that some increase in grant is necessary to enable the universities to maintain the present level of activity

When it comes to development, I have had to take account of two conflicting considerations The first is the growing number of qualified applicants for admission to the universities, and the importance of their output of graduates at a time when the need for highly trained people in business, industry, administration, teaching, and research is increasing and when the country s future requires us to keep in the forefront of scientific and technological development The second is the financial and economic difficulties of the country, which call for general restraint

Taking these factors into account, the amounts which I propose to invite Parliament to vote for recurrent grant for the five university years beginning on Aug 1 next are as follows

1957–58	£30,600 000
1958–59	£32 300 000
1959–60	£34 350 000
1960–61	£36 750 000
1951–62	£39 500 000

These sums do not include provision for non recurrent grants towards capital expenditure, and they take no account of the recently announced improvements in academic salaries

QUESTION TIME

Propaganda Against Smoking

Dr Barnett Stross asked the Parliamentary Secretary to the Ministry of Education whether he would have made a film suitable for showing to school-children at an appropriate age and to all school leavers, which will advise them of the dangers of smoking to health —Sir Edward Boyle replied No, Sir Dr Stross I wonder why we have had such an answer ? Is it not apparent that the Ministry has issued instructions to school-teachers enabling them to read an article in the particular textbook to which I am referring, so that they can warn children ? If this is sincerely meant, why not a visual aid, in view of the importance of the disease which we are discussing ?—Sir Edward Boyle I understand that a film of this kind has been made in the United States, but I rather doubt if it would be acceptable as suitable for showing to school-children in this country Mr M Stewart Could not the Parliamentary Secretary take a slightly less negative attitude about this ? Even if there is something in it which makes this film unsuitable, cannot the Ministry consider positively what it can do on this question ?—Sir Edward Boyle I think that the approach to that topic in the Department's handbook on health education shows the lines on which we are thinking, but certainly I take note of what the hon Member has said

Parental Means Test and Scholarships

Mr Frank Beswick asked the Minister if he would take steps, by revising the present parental means test procedure, to ensure that grants and awards to university entrants are not reduced —Sir Edward Boyle replied The Government do not at present intend to introduce any amending legislation. Mr Emanuel Shinwell Does the Minister realise that there are many parents anxious to provide higher education at the universities for their children who are finding great difficulty because of the operation of the means test ?—Sir Edward Boyle Later this year my noble Friend will be examining the arrangements for assessing university awards, in consultation with representatives of the universities and the local authority associations But I cannot, I am afraid, say more this afternoon Mr Beswick Does the Minister appreciate that a means test cutting across an ability test is no less objectionable because it hits hardest at the so called middle classes or professional classes ? Would he bear in mind also that the reform asked for in these questions would find much wider acceptance than any proposal to give an income tax allowance in the matter of education ?—Sir Edward Boyle This is I agree an important subject, but I cannot go further this afternoon Lord Balniel Can the Minister say how much it would cost the taxpayer to abolish this means test ?—Sir Edward Boyle I am told that the cost of abolishing the test for all university awards would be about £3$^{1}/_{2}$ million this year in respect of United Kingdom students at universities in England and Wales

Earnings of Mental Patients

Mr N N Dodds asked the Minister of Health what progress he had made in his investigations into the payment by mental patients engaged in remunerative employment outside the institution who are required to make payments from their earnings towards their maintenance as inpatients, and if a decision had yet been reached as to whether or not the patients were, in future, to be given receipts for the money they were required to pay —Mr Dennis Vosper replied My inquiries have shown that in nearly all cases receipts are given to these patients in mental hospitals, but less frequently in mental deficiency hospitals, where the wages are often paid direct to the hospital authority on behalf of the patients and receipts are given to the employers I propose to ask hospital authorities to give receipts in future in all cases where money is paid over by the patient himself and the authority is satisfied that he is capable of understanding the nature of the document

Rampton State Institution

Dr Donald Johnson asked the Minister the total number of inmates of Rampton State Institution, and how many of these had had criminal convictions —Mr Vosper replied. 1092 Full information is not available as to how many have had criminal convictions, but 539 were dealt with as mental defectives either by the courts or by the Secretary of State whilst being detained in prison, approved schools, or elsewhere Dr Johnson Is the Minister aware of the anxiety of many people that inmates who have criminal convictions are mixed with many others who have no criminal convictions of any kind ? Will he give this matter his special attention when considering the forthcoming report ? Mr Vosper I will do that, of course, but all the inmates of Rampton have this in common, that they are of violent propensities, and it would be very difficult to separate the two categories which my hon Friend has in mind

Strontium Level in Bones of Children

Mrs Butler asked the Minister what was the latest available figure indicating the level of strontium in the bones of young children, and the amount by which this had increased since the figure for the level at November, 1955, was published in the Medical Research Council's report of June, 1956 —Mr Vosper replied The average level of strontium 90 found during 1956 in the bones of young children in the United Kingdom was 0 67 unit. The highest single level observed was 1 3 units, a level which does not differ significantly from the maximum of 1 2 units given in the report published by the Medical Research Council in June, 1956 Mrs Butler Is the Minister aware that when the original measurements were taken only four hydrogen bombs had been exploded ? It is believed that sixteen tests have now taken place Is it not the case that the measurements taken in the United States six months ago showed a very high and rising level of strontium 90, which has been described as the most dangerous poison in the world ? Will he assure the House that he will keep this matter under very close and constant review ? Mr Vosper The early part of the hon Lady's question goes somewhat beyond my responsibility There has been little or no change during the year in question and, of course, the matter is very much under review

Mr Somerville Hastings In giving the very careful consideration to this matter which I know he is giving it, will the right hon. Gentleman remember that when X rays were first used in this country no one realised that there was any danger, that it was not until there had been many deaths from carcinoma of the hands and other parts of the body that the damage was appreciated ? Will he watch this matter with very great care ? Dr Edith Summerskill In view of the increasing concern of reputable scientists about the hazards to life of these bomb explosions has the Minister taken any advice more recent than that of the Medical Research Council last June ? Mr Vosper *The original* question asked for the latest available figure, which I have given I have said that investigation is continuing and that the matter is being watched very closely

Transistor Hearing-aids

Field trials began *this month* on the transistor hearing-aid designed for the Medical Research Council.

Obituary

ESTHER LILLIE CARLING

M D Brux., L S A

The story of Esther Carling's life is also a great part of the story of the sanatorium movement in this country. She treated her first patient by the open-air method in a farmhouse in the late 'nineties. By the time that she retired in 1938 over 10,000 tuberculous patients had passed through her hands, and the sanatorium which she had founded had 180 beds, including a children's section, and a farm of 60 acres.

She was born in 1870, the daughter of William Colebrook, a some-time mayor of Reading who took a keen interest in the problems of sanitation. She studied medicine at the Royal Free Hospital and qualified in 1896. From the start she was attracted to the public-health side of medicine. Tuberculosis was one of its most urgent problems, and in the village practice which she started at Peppard in Berkshire she was soon at grips with it. Dr Hastings Gilford of Reading asked her if she could improvise open-air treatment for one of his patients with phthisis. Good results had been claimed for this therapy by Walther and others in Germany, and it appealed to Dr Carling as more likely to succeed than bottles of medicine. So she arranged to treat the patient at a neighbouring farmhouse. The patient made a good recovery, and two friends who had visited her and been fired by Dr Carling's enthusiasm for the new therapy sent her a cheque for £2000 to cover the cost of treating other patients. These were not slow to arrive, and temporary shelters were designed and built for them. That was the beginning of Kingwood Sanatorium, to which Maitland House was added a little later, with money also supplied (unasked) by the friends of another patient.

Every year Dr Carling's work grew, until in 1911 she had 70 patients under treatment. In that year John Burns paid her a surprise visit. He was then president of the Local Government Board, and much concerned about tuberculosis. He also foresaw that under the National Insurance Act a considerable sum of money would be available for a more vigorous campaign against the disease. After his visit he asked her if she would consider handing over the financial responsibility for the sanatorium to the Berks and Bucks county councils, and become its medical director.

During the 1914–18 war Dr Claude Lillingston joined the staff at Peppard Sanatorium, as it was now called, and enabled Dr Carling to add to her responsibilities there tuberculosis-dispensary work in the neighbouring counties. Of their effective, if improbable, partnership he writes:

> *It was arranged that we should take duty on alternate days. Every other day she was to absent herself in order to act as district tuberculosis officer. At that time the pick-and-shovel school of auto-inoculation by graduated labour still enjoyed a certain vogue. It appealed to the enterprising element in Dr Carling's character, and she encouraged work by her patients on the sanatorium garden. At the same time I was labouring under the conviction that rest in general, and immobilisation of a tuberculous lung in particular, was the best road to recovery. With these bees buzzing in our respective bonnets, we sailed into a happily lop-sided partnership which lasted three years. On her days on duty, Dr Carling would send her patients to work in the garden. Next day I would send them back to bed. Why did she never bash out my brains? Perhaps what saved them was her love for her ailing fellow beings—a love which left no room for wounded amour-propre.*

> *The determination and courage with which Dr Carling faced and overcame difficulties were somehow communicated to her patients, and the warmth of her personality drew the affection and loyalty of her staff. But she was much more than the head of a successful sanatorium. For many years she brought her common sense and her humanity to the work of a magistrates' court. She found time to raise a family and to receive many visitors, including Sir William Osler, at her home at Peppard. Perhaps the most important and enduring of her interests was the welfare of nurses. One of her characteristically pungent letters, which we published in 1930, led to the appointment of the Lancet Commission on Nursing, and in her last letter in 1952 she was still sharply protesting, this time against the exposure of nurses in their 'teens to the risk of infection.*

Dr Carling would have been the first to point out how much she and her sanatorium owed to her husband, Henry Carling, and to his talent for administration. Of their marriage a friend writes:

> *In many respects the Carlings were as unlike as husband and wife can possibly be. She was glowing, impulsive; he was cool, methodical. Her sense of injustice over an abstract problem such as women's suffrage, or her outraged sense of compassion over some underdog in trouble, would set her expressive brown eyes ablaze, her small frame aquiver. The same incident would start him on a carefully planned campaign of rescue of that same underdog. She drove through life as she drove her car—so as to get there, without any undue attention to mechanical details. Her motto was "Leave it to Henry," who rose to every emergency, whether she had rammed the buttocks of a cow with her car or got into some administrative cobble at the sanatorium.*

Her husband's death soon after the last war left her bereft, and her active mind chafed against the physical restrictions of old age. She died on March 18 in Ipswich.

Dr H C ELDER

C K McD. writes:

Dr Elder was one of those medical teachers who had a great influence on earlier generations of Edinburgh students and graduates. His was no parochial learning and his dissertations on tuberculosis showed a firm and discriminating grasp of the world literature and activities. His clinical ability was prodigious, and to attend him on ward rounds or clinics was sometimes exhausting, since one's concentration was kept continually on the stretch. But it was a rewarding and unique experience, often followed by great hilarity when some of his shafts of wit (and occasional darts of reproof) were recalled, for his breadth of culture allowed him to couch his technical utterances in distinctive terms, but always charmingly. He brought a grace and character to medicine which we will not easily forget.

Medicine and the Law

Procedure for Intrathecal Injections

As a result of the death of a patient following an injection of penicillin, a regional hospital board has issued directions with regard to the administration of intrathecal injections. Hospital management committees in the region have been informed that, when such injections are to be given, the quantities should be checked by another doctor or a State-registered nurse or a student nurse, as well as by the doctor who is to administer the injection; a book should be signed to record that this has been done and the quantity administered. The regional board add that this rule is not intended to imply that a nurse should check the doctor's prescription. Hospital management committees have also been asked to review critically in consultation with matrons and (where appropriate) with chief male nurses their arrangements for checking the giving of drugs, especially when given intravenously.

The Medical Defence Union has protested to the Ministry of Health, and is advising its members to oppose the introduction or observation of such rules on the ground that they are an interference with clinical freedom: the responsibility for taking appropriate precautions with regard to any medical or surgical operation belongs, it says, inalienably to the doctor carrying out the procedure. Dr Robert Forbes, secretary of the M.D.U., has pointed out[1] that, although the rule relates at the moment only to intrathecal injections, in a short time it might relate to many other forms of injection.

Notes and News

GASTRO-ENTEROLOGY AT THE CENTRAL MIDDLESEX

ONE of the chief centres of gastro-enterology in this country is the department at the Central Middlesex Hospital, London, N.W.10, of which Dr F. Avery Jones is the physician in charge. Since last week this department has had premises more in keeping with its importance and international reputation. In close association with the ward of 50 beds, there will now be four laboratories, an endoscopy theatre, facilities for radiological investigations, a library and conference room, and offices. To allow for this development the Nuffield Foundation has given £6500 for the building, and the Medical Research Council £6100 for equipment, and the North West Metropolitan Regional Hospital Board has provided the balance of £2200. All who attended the opening on March 15 must have felt that astonishingly good value has been obtained for the money spent. Indeed in relation to the cost of many other buildings today, it is hard to see how so small a sum has been made to buy such capacious premises so well finished and attractive.

Explaining why a surgeon, Sir Gordon Gordon-Taylor, had been invited to perform the opening ceremony, Mr Maurice Orbach, M.P., chairman of the management committee, said that the department had always depended on coöperation between physicians and surgeons, and the physicians wanted to show their recognition of the partnership. He also spoke of the partnership of the Central Middlesex with the Middlesex Hospital, and its wish to emulate Sir Gordon in maintaining links with the Commonwealth.

Sir Gordon Gordon-Taylor, who said it was fifty years since he performed his first gastro-enterostomy, described gastro-enterology as now far more than a province—"really an empire of its own." Dr Avery Jones's department had become a veritable mecca and he hoped that in the new premises the cause and cure of peptic ulcer would now be discovered. Alarmed by the present prospect that surgery might otherwise reduce this nation to "a cohort of gastric geldings," he pointed out that an army fights upon its stomach "and how are we to fight the next war if most of us have none to fight upon?"

Dr Avery Jones recalled how the department had been started when in 1937 Dr Horace Joules segregated 50 beds for gastro-enterology, and went on to speak of the strong team formed by his colleagues. Dr T. D. Kellock and Dr Richard Doll have now been joined by Dr E. N. Rowlands, working half time in the department for the Medical Research Council. Dr Margot Shiner is developing the technique of intestinal biopsy, and the team has invaluable help from Dr Frank Pygott in radiology and from Dr Allan Gray, Dr George Discombe and Dr R. A. B. Drury in pathology.

A PIONEER IN MICROBIOLOGY

Agostino Bassi, who died a hundred years ago, was a pioneer in microbiology. He discovered the pathogenic organism of silkworm disease and announced his findings to a group of professors at the University of Pavia in 1834. On that occasion Bassi revealed for the first time that the disease was caused by a vegetable parasite which could be destroyed by the use of certain chemical and physical agents. According to Bassi, contagion and epidemics were caused "exclusively by living microscopic beings which are extraordinarily prolific and capable of being communicated directly or indirectly to animals in general, man, insects, wind or water, sensible to climatic variations and the state of reception of the population among which they are transplanted." Having confirmed his assumptions with the discovery of the first agent of positive pathogenic nature, he organised for the first time a prophylaxis based on caution and sterilisation.

Dr Giovanni Arcieri has rightly commemorated the centenary of Bassi's death with a specially written brochure in English.[1] He claims that Bassi was the real founder of microbiology and not merely a forerunner of Pasteur. Unfortunately he has allowed his enthusiasm too much freedom. It is difficult to agree with his contention that Pasteur, Koch, Metchnikoff, Klebs, and other eminent scientists would not be known as such without Bassi's discovery, or that the discovery should have been acknowledged by the cinema industry. Nevertheless this is an interesting biography, for it includes accounts of Fracastoro, "the first to formulate the true epidemiological doctrine," Redi, "who first undermined the theory of spontaneous generation," Cestoni, "who discovered in 1687 the parasite of scabies," and Spallanzani, "the father of experimental biology."

STAFFING THE MENTAL HOSPITAL

THE difficulty that many provincial institutions have in attracting young doctors is all too well known, and it will somehow have to be overcome. Recording that at Moorhaven Hospital, South Devon, the newly established posts of senior registrar and junior hospital medical officer remained empty for many months, Dr Francis Pilkington, the physician-superintendent, points out that one remedy is to provide good accommodation at low rents.[1] Photographs of some of the houses provided for the hospital's physicians are reproduced in his report.

Contrary to what might be expected, the fact that Moorhaven Hospital is a training centre for psychiatrists makes the shortage of staff more rather than less acute. For this there are several reasons. Firstly, a mental hospital which undertakes training always has a proportion of inexperienced doctors on its staff; secondly, the staff are more changeable and there may be gaps between the appointments; thirdly, the trained must devote some of their time to teaching the untrained; and fourthly, the untrained need much time off for studying privately or attending courses. Hence, as Dr Pilkington says, medical establishments must be more liberal in training hospitals than in others.

JOINT CONTRACTING FOR HOSPITAL SUPPLIES

IN December, 1954, the Central Health Services Council appointed a committee, under the chairmanship of Sir Frederick Messer, to investigate various aspects of hospital supplies. The committee's interim report[2] is mainly concerned with joint contracting schemes, which have already been operating in a few cases.

The committee suggests that the existing evidence shows economic advantages in bulk buying, particularly of drugs. Joint contracting might lead on the one hand to increases in range and quality, or on the other hand to drab uniformity. The committee thinks that uniformity does not matter for supplies which do not affect the service to the patient. From joint contracting it expects an improvement of standards, but no tendency to over-estimate and (with proper planning) no storage difficulties; some hospitals might hold stocks for others that have not enough storage space.

The committee advises all hospital authorities to adopt joint contracting schemes, which yield the advantages of large-scale buying without damaging the autonomy of hospital groups. The Minister has asked hospital authorities to review their arrangements in the light of the report.

University of Cambridge

On March 9 the following degrees were conferred:

M.D.—T. M. D. Gimlette, K. E. Halnan, A. S. Herington, J. O. Robinson, J. R. Seale, H. B. L. Williams.

M.Chir.—*C. H. Kinder.

M.B.—*Chit Chan Gunn.

* By proxy.

University of London

On Feb. 27 the degree of M.D. was conferred on Derrick Rowley.

University of Leeds

The council has accepted a grant from the Nuffield Provincial Hospitals Trust of £8500 a year for two years to enable the university, through the department of adult education and extramural studies, to promote a pilot scheme of courses of study for hospital administrators. The scheme will be an experiment in the design and operation of residential courses for senior members of the staffs of hospitals and of regional hospital boards. The courses will probably last not less than four weeks, and will be staffed by a full-time director of studies, two other full-time senior staff members, and part-time lecturers. The director and his assistants will also undertake research on training for hospital administration.

> It was arranged that we should take duty on alternate days Every other day she was to absent herself in order to act as a district tuberculosis officer At that time the pick-and-shovel school of auto inoculation by graduated labour still enjoyed a certain vogue It appealed to the enterprising element in Dr Carling s character, and she encouraged work by her patients on the sanatorium garden At the same time I was labouring under the conviction that rest in general, and immobilisation of a tuberculous lung in *particular*, was the best road to recovery With these bees buzzing in our respective bonnets, we sailed into a happily lopsided partnership which lasted three years On her days on duty, Dr Carling would send her patients to work in the garden Next day I would send them back to bed Why did she never bash out my brains ? Perhaps what saved them was her love for her ailing fellow beings—a love which left no room for wounded *amour propre*

The determination and courage with which Dr Carling faced and overcame difficulties were somehow communicated to her patients, and the warmth of her personality drew the affection and loyalty of her staff But she was much more than the head of a successful sanatorium For many years she brought her common sense and her humanity to the work of a magistrates' court She found time to raise a family and to receive many visitors, including Sir William Osler, at her home at Peppard Perhaps the most important and enduring of her interests was the welfare of nurses One of her characteristically pungent letters, which we published in 1930, led to the appointment of the *Lancet* Commission on Nursing, and in her last letter in 1952 she was still sharply protesting, this time against the exposure of nurses in their 'teens to the risk of infection

Dr Carling would have been the first to point out how much she and her sanatorium owed to her husband Henry Carling, and to his talent for administration Of their marriage a friend writes

> In many respects the Carlings were as unlike as husband and wife can possibly be She was glowing, impulsive He was cool, methodical Her sense of injustice over an abstract problem such as women's suffrage, or her outraged sense of compassion over some underdog in trouble, would set her expressive brown eyes ablaze, her small frame aquiver The same incident would start him on a carefully planned campaign of rescue of that same underdog She drove through life as she drove her car—so as to get there, without any undue attention to mechanical details Her motto was "*Leave it to Henry*," who rose to every emergency, whether she had rammed the buttocks of a cow with her car or got into some administrative cobble at the sanatorium

Her husband's death soon after the late war left her bereft, and her active mind chafed against the physical restrictions of old age. She died on March 18 at Ipswich

Dr H C ELDER

C K McD writes

Dr Elder was one of those medical teachers who had a great influence on earlier generations of Edinburgh students and graduates His was no parochial learning and his dissertations on tuberculosis showed a firm and discriminating grasp of the world literature and activities His clinical ability was prodigious, and to attend him on ward rounds or clinics was sometimes exhausting, since one's concentration was kept continually on the stretch But it was a rewarding and unique experience, often followed by great hilarity when some of his shafts of wit (and occasional darts of reproof) were recalled, for his breadth of culture allowed him to couch his technical utterances in distinctive terms, but always charmingly He brought a grace and character to medicine which we will not easily forget

Medicine and the Law

Procedure for Intrathecal Injections

As a result of the death of a patient following an injection of penicillin, a regional hospital board has issued directions with regard to the administration of intrathecal injections Hospital management committees in the region have been informed that, when such injections are to be given, the quantities should be checked by another doctor or a State-registered nurse or a student nurse, as well as by the doctor who is to administer the injection , a book should be signed to record that this has been done and the quantity administered The regional board add that this rule is not intended to imply that a nurse should check the doctor's prescription Hospital management committees have also been asked to review critically in consultation with matrons and (where appropriate) with chief male nurses their arrangements for checking the giving of drugs especially when given intravenously

The Medical Defence Union has protested to the Ministry of Health, and is advising its members to oppose the introduction or observation of such rules on the ground that they are an interference with clinical freedom the responsibility for taking appropriate precautions with regard to any medical or surgical operation belongs, it says, inalienably to the doctor carrying out the procedure Dr Robert Forbes, secretary of the M D U , has pointed out[1] that, although the rule relates at the moment only to intrathecal injections, in a short time it might relate to many other forms of injection

A CONCENTRATE OF HUMAN ANTIHÆMOPHILIC FACTOR

ITS USE IN SIX CASES OF HÆMOPHILIA

MEDICAL RESEARCH COUNCIL GRANTEE

From the Lister Institute of Preventive Medicine, London

UP to 1954, the only effectual method of treating hæmorrhage in hæmophiliacs was the transfusion of fresh blood, fresh plasma, or plasma separated from fresh blood and quickly frozen and stored at –20°C These materials still have to be used in most cases, despite the danger that, because of the low antihæmophilic potency of human blood or plasma, however recently drawn, the circulation may be overloaded before hæmostasis can be achieved

The preparation of antihæmophilic factor of very high potency from animal blood by Macfarlane et al (1954) was a substantial advance However, since such products consist of heterologous protein, they may provoke an antigenic response in the recipient—a dangerous state that precludes the repeated administration often essential in the management of hæmophiliacs

It has long been evident that a potent preparation of human antihæmophilic factor would be very valuable, but the instability and the relatively low level of the activity in human plasma are disadvantages which have been difficult to overcome In this paper we describe the preparation of a concentrate of human antihæmophilic factor, and its use in the treatment of six cases of hæmophilia, in some of which fairly radical surgery was undertaken

Attempts to separate the antihæmophilic factor from other constituents of plasma have until recently been restricted by the lack of an adequate method for the assay of antihæmophilic activity The development of the thromboplastin-generation test by Macfarlane and his colleagues (Biggs and Douglas 1953, Biggs et al 1953, 1955), in providing a reliable in-vitro assay, made purification studies possible, and protein fractions possessing a very high antihæmophilic potency were separated, by salting out techniques, from the plasmas of several domestic animals by the Oxford workers (Bidwell 1955) We have preferred to use an assay, devised by one of us (Wolf 1956), depending on the change induced in the prothrombin conversion ratio of an artificial hæmophilic substrate by the addition of substances having antihæmophilic activity This method was used to measure the activity of protein fractions separated from normal human plasma, and to study the effect of preparations of antihæmophilic factor on the activity in the plasma of hæmophilic patients undergoing treatment

The antihæmophilic activity of citrated human plasma is reported to decrease rapidly unless the plasma is expeditiously separated from the formed elements of blood and then frozen to –20°C We found that the antihæmophilic activity fell by 10–20% in sixteen hours, and by 50% after four days when trisodium citrate plasma was stored at 2–4°C Consequently speed of operation is a major consideration, at least in the early stages of fractionation, if reasonable yields of antihæmophilic factor are to be obtained

During the serial fractionation of normal human plasma proteins, using water-miscible solvents as precipitants, the first crude fraction removed contains most of the fibrinogen and some of the antihæmophilic factor (Kekwick and Mackay 1954) In the present experiments the conditions were modified to produce a maximal precipitation of the antihæmophilic factor in the fibrinogen fraction , the potency of this crude fraction was increased by simple ancillary treatment The experiments leading to the definition of these conditions will be described elsewhere

Method of Preparation

Blood taken into 100 ml of 3% (*w*/*v*) trisodium citrate up to a total volume of 540 ml is cooled as soon as possible to 2–4°C and centrifuged for an hour at 1500 r p m at 0 0 ± 0 2°C preferably within three hours of the bleeding The plasma is siphoned from the layer of red cells, centrifuged as before for thirty minutes, and poured cautiously from the slight residue of platelets and cells

To the pooled twice centrifuged plasma is added an equal volume of distilled water at 0°C The diluted plasma is cooled to –0 5°C, and 11 vol % of cold ethyl ether is added slowly with adequate stirring, the temperature of the mixture being maintained between –0 5°C and –1 0°C during this addition When all the ether has been added, the mixture is allowed to equilibrate overnight (sixteen hours) at 0°C

The clear supernatant solution is siphoned off as far as possible, and the residual precipitate and supernatant fluid are stirred to a uniform sludge, which is then centrifuged for thirty minutes at 1500 r p m at 0 0 ± 0 2°C The packed precipitate is suspended in 30% of the plasma volume of the following solution previously cooled to 0°C sodium chloride 4 25 g and trisodium citrate 1 85 g made up to 1 0 litre with distilled water and 80 ml of ethyl ether added—and centrifuged as before for thirty minutes The washed precipitate is suspended in 50% of the plasma volume of distilled water at 0 0–0 5°C and centrifuged as before for forty-five minutes

The twice washed precipitate is then dissolved in sufficient of the following solution at 25°C to give a total volume equal to 10% of the initial plasma volume sodium chloride 17 0 g and trisodium citrate 7 4 g made up to 1 0 litre with distilled water

The precipitate, when gently agitated, dissolves completely in ten to fifteen minutes, giving a colourless and slightly opalescent solution This is frozen immediately in 100 ml quantities to –20°C in the final containers for freeze drying, and the small samples required for assay are similarly treated if the assays cannot be made at once

The equipment and solutions used were all sterile, and the preparative procedures were carried out under aseptic conditions (see Kekwick and Mackay 1954), consequently it was unnecessary to sterilise the final solution by filtration before freeze-drying Nevertheless the product passed the sterility tests appropriate for substances used for parenteral injection in man

Some Characteristics of Material used for Clinical Test

On the basis of in-vitro assay, the antihæmophilic activity in the final product has consistently been not less than 85% of the starting material, and the potency in terms of activity per mg of protein has been 20–25 times that of fresh plasma

The product is dissolved in a volume such that the resulting solution has approximately ten times the activity of normal plasma , the total protein content is about 2 2 g per 100 ml and the viscosity so low as to present no problem during administration Such solutions can be held frozen at –20°C or dried from the frozen state with negligible loss in activity Freeze-dried material has been stored at room-temperature for six months with only slight loss in activity, and it redissolves completely in twenty to twenty five minutes when the appropriate volume of distilled water is added at room-temperature

Like most of the preparations of antihæmophilic factor so far prepared in quantities adequate for clinical use, this human preparation contains a large proportion of fibrinogen , about 70% of the total protein appears in the clot formed when thrombin is added to a suitably diluted solution The separation of fibrinogen from antihæmophilic factor by a procedure ensuring a good recovery of each is a problem of some complexity The preparation was therefore tested clinically in its relatively

University of Sheffield

Dr I B Sneddon has been appointed part-time lecturer in dermatology

University of Edinburgh

Sir Howard Florey, F R S, will be among those who will receive the honorary degree of LL D at a ceremony to be held on July 5

Royal College of Surgeons of England

At a meeting of the council on March 14, with Sir Harry Platt, the president, in the chair, Mr A L d'Abreu and Mr E G Muir were admitted to the court of examiners

The following Sir Arthur Sims Commonwealth travelling professors were appointed for 1958 Prof M L Rosenheim to visit Australia and New Zealand and Prof R M Janes (Toronto) to visit parts of Africa

The Hallett prize was awarded to Dr S K Nau (Agra), and the Macloghlin scholarship to F R Jackaman (Queen Elizabeth's School, Barnet)

Scottish Regional Hospital Boards

The Secretary of State for Scotland has reappointed the chairmen of the five regional hospital boards for a further three years

Biochemical Society

The annual general meeting of this society will be held in the Department of Biochemistry, University College, London, W C 1, on Thursday, March 28, at 10 A M

Christian Medical Fellowship

At a meeting of this fellowship to be held on Wednesday, March 27, at 8 15 P M, at the Royal Empire Society, Northumberland Avenue, London, W C 2, Mr Harold Dodd will speak on the Doctor as a Person

International Cancer Congress

This congress will be held in London from July 6 to 12, 1958, under the presidency of Sir Stanford Cade Further particulars may be had from the office of the congress, 45, Lincoln's Inn Fields, W C 2

Diet and Coronary Disease

Prof John Yudkin will speak on this subject after the annual general meeting of the Nutrition Panel of the Food Group of the Society of Chemical Industry, which is to be held at 14, Belgrave Square, London, S W 1, at 6 15 P M, on Wednesday, April 10

Study Course on W H O

The World Federation of United Nations Associations will hold a study course on the World Health Organisation in Geneva from May 6 to 15, simultaneously with the World Health Assembly Further information may be had from the federation, 1, avenue de la Paix, Geneva, Switzerland

Dental Implant Society

This society is holding a meeting at 1, Wimpole Street, London, W 1, on Wednesday, May 15, at 7 P M, when Prof Talmage Read will speak on subperiosteal dental implants, and Mr Boris Trainin, L D S, will show a colour film illustrating surgical and laboratory techniques for a new type of implant Non-members who wish to attend should write to the hon secretary of the society, 109, Harley Street, W 1

International Nutrition Congress

A congress is to be held, under the auspices of the International Union of Nutritional Sciences, in Paris from July 26 to Aug 1 Further information about the congress may be had from Prof E Terroine, Centre National de Coordination des Études et Recherches sur la Nutrition et l'Alimentation 71, Boulevard Pereire, Paris, 17e, and about the union from the secretary-general Mr Leslie J Harris, D SC, Dunn Nutritional Laboratory, Milton Road, Cambridge

Dr Ronald Woolmer director of the department of anæsthetics in the Royal College of Surgeons of England is visiting medical research centres and departments of anæsthetics in the United States and Canada with a grant from the Rockefeller Foundation

fourth day circulatory failure again threatened. On the fifth day 200 ml. of concentrate (batch EF 29) was transfused (table, episode 1a). During the following two days 200 ml. of EF 29 and 1 pint of whole blood were given daily. Since there was no further evidence of bleeding, therapy was discontinued after the second day, and the patient was then making a satisfactory convalescence.

A week later, the patient having recovered, an experiment was made to compare the change in A H F level produced by the concentrate and by fresh plasma (table, episodes 1b and c). The A H F level was determined before and after administering 200 ml. of concentrate EF 29, and next day similar measurements were made before and after the transfusion of 420 ml. of fresh frozen plasma.

Plasma volume was estimated on the basis of 76 ml. of whole blood per kg. body-weight. Hæmatocrit during episode of bleeding was 25%, and during convalescence 40%. In estimating the plasma volume these values were multiplied by 0·90 to correct for trapped plasma and for non-uniform distribution of erythrocytes in the vascular system (Mollison 1956).

Episode 2

Oct. 31.—Admitted from outpatient department, which he attended for follow-up, having been found pale and with symptoms of a recent acute blood-loss. Hæmoglobin 45%, hæmatocrit 28%. Stool contained blood. Given 300 ml. concentrate EF 39 immediately, followed by 2 pints of fresh blood. There was no transfusion reaction.

Nov. 1.—Given 900 ml. of fresh frozen plasma. In the next four days given a total of 1980 ml. of fresh frozen plasma. Melæna stools disappeared, and transfusion therapy discontinued. Patient made an uninterrupted recovery.

Episode 3

Nov. 21.—Dental extraction. Hæmoglobin before operation 60%, hæmatocrit 34%. Before operation 300 ml. of concentrate LF 43 given intravenously (table, episode 3). No transfusion reaction. General anæsthetic given through intratracheal tube. Two teeth and twenty-one roots were extracted; one root had a medium-sized dental cyst at its base, which was curetted. Dried human thrombin was introduced into the cavities, which were then lightly packed with sterile alginate wool, and dental splints were then applied. No undue hæmorrhage occurred at the operation.

Nov. 22.—No hæmorrhage or oozing, but 200 ml. of concentrate LF 45 was given to maintain A H F level. Patient complained of pains in back during transfusion.

Nov. 23.—No hæmorrhage or oozing; 200 ml. of concentrate EF 45 given, and patient again had pain in back during transfusion.

Nov. 24.—No hæmorrhage or oozing. Further 200 ml. of concentrate FF 45 given. Pains in back and chest during transfusion relieved by intravenous pethidine.

Nov. 25.—No hæmorrhage or oozing during day, but oozing from one socket started in evening. During night 600 ml. of fresh frozen plasma arrested the oozing.

Nov. 26.—Given 600 ml. of fresh frozen plasma. Dental splints removed; no hæmorrhage or oozing.

Nov. 27 and 28.—No hæmorrhage or oozing but given 600 ml. of fresh frozen plasma each day.

Nov. 29.—Packed red cells from two pints of blood given. No hæmorrhage or oozing. End of transfusion therapy.

Dec. 4.—Patient discharged from hospital.

Case 2.—A man aged 41, weight 8 st. Previous history of moderately severe hæmophilia, with joints showing chronic hæmorrhagic joint disease. Family history of hæmophilia. Admitted to hospital for extraction of tooth.

Immediately before the extraction he was given a transfusion of concentrate FF 20 (180 ml.), and the tooth was extracted under gas and oxygen. After the extraction the cavity was packed with 'Oxycel' gauze and a dental splint was applied, which was removed four days later. No bleeding whatsoever took place immediately after the extraction or subsequently up to the patient's discharge seven days later.

Laboratory findings.—Total blood-volume (determined by Dr. J. H. Crookston using chromium-labelled red cells) 3650 ml. Plasma-volume 2200 ml. Hæmatocrit 42·5%. Hæmoglobin 12·5 g. per 100 ml. For other data see table.

Case 3.—A man aged 40, weight 8 st. History of severe classical hæmophilia, with multiple and severe chronic hæmorrhagic joint disease. Admitted to hospital with spontaneous hæmorrhages into both wrists, muscles of both forearms, and both knee-joints, occurring over previous three weeks. On admission there were signs of active bleeding into the knee-joints, the pain from which had prevented him from sleeping on the previous three nights.

He was given a transfusion of concentrates LF 29 and LF 31, total volume 300 ml. After an hour the pain in both knee-joints had subsided, and the same night he slept well without sedatives. His subsequent recovery was uneventful, and he was discharged from hospital after seven days.

Laboratory findings.—Blood-volume measured as in case 2 with chromium-labelled red cells. Hæmatocrit 43·5%. Plasma-volume 2250 ml. (See table.)

Case 4.—A boy, aged 6, weight 42 lb. Family history of hæmophilia. Admitted to hospital with injury to left leg; hæmorrhage into ankle and knee, calf muscle, and muscle of thigh.

After a transfusion of 100 ml. of concentrate EF 31 he had a severe rigor lasting twenty minutes. Some of the same batch of concentrate had been administered to case 3 without untoward effect. A test for pyrogen was negative. Considerable clinical improvement followed the transfusion, and there was no further hæmorrhage.

Laboratory findings.—Plasma-volume 1070 ml. estimated from weight and hæmatocrit. Hæmatocrit 28%. Hæmoglobin 61%.

Case 5.—A man, aged 28, weight 11 st. 6 lb. Previous history of mild hæmophilia, but no family history. Various episodes of bleeding from 1947 onwards. In July, 1956, while abroad, he had a purulent discharge from his rectum. An incision to drain the abscess led to a persistent discharge of pus into his rectum. He was flown to England and admitted to hospital for radical treatment.

Oct. 11, 1956.—Given 300 ml. concentrate FF 37. Under general anæsthesia external drainage of the abscess was established. A broad tract was cut to the abscess by removing about 2½ inches of buttock tissue and part of the superficial anal sphincter. There was no undue hæmorrhage during the operation (performed by Mr. G. A. Jemson). No hæmorrhage or further treatment until Oct. 15.

Oct. 15.—Given 200 ml. of concentrate EF 37. Wound then inspected by surgeon and repacked. During the night hæmorrhage occurred and hæmoglobin dropped from 77 to 45% and hæmatocrit fell from 41 to 23%.

Oct. 16 to 22.—Patient received successively 3 pints of stored blood (Oct. 16), 2 pints of fresh blood (Oct. 17), 2 pints of fresh blood (Oct. 19), 2½ pints of stored blood (Oct. 21), and 2 pints of stored blood (Oct. 22). After this no further hæmorrhage took place, and the patient made an uninterrupted recovery, being discharged on Dec. 20.

Laboratory findings.—Plasma-volume estimated from weight and hæmatocrit. Hæmatocrit before first injection on Oct. 11 was 44% (uncorrected) and before second injection on Oct. 15 41% (uncorrected).

Case 6.—A boy, aged 18, weight 10 st. Moderately severe hæmophilia. No family history of hæmophilia. He had been admitted twenty-four times for episodes of bleeding, including hæmorrhages into joints causing limited movement of right knee and left elbow.

On Oct. 25, 1956, he was admitted for extraction of the first molar in the right lower jaw, which had an underlying abscess. Local anæsthetic. 280 ml. of concentrate EF 41 was given immediately before the extraction and was followed by an urticarial rash. Difficult extraction, dental splint applied. Oozing from socket for an hour after extraction, and slight oozing during night. No further bleeding until evening of Oct. 28. On Oct. 29 100 ml. of IF 31 and 100 ml. of IF 39 were given, and dental splint was removed. Another urticarial rash developed, with pruritus. Rash was arrested with 50 mg. of promethazine. Bleeding was arrested for twenty-four hours.

After this, intermittent oozing from socket recurred and was controlled by digital pressure and the topical application of thrombin. On Nov. 8 the socket was packed. On Nov. 11 a substantial hæmorrhage took place. On Nov. 12 500 ml. of fresh whole blood followed by 500 ml. of fresh plasma was given. No further hæmorrhage. The patient was discharged on Nov. 18. The plasma-volume (estimated with Evans blue) was 2350 ml.

Discussion

A potent preparation of antihæmophilic factor would obviously be of great value, in the management of hæmophiliacs, for preventing the development of

impure state although, with a purification factor of only 20–25 fold, it was realised that 100 ml of solution would be needed *to* produce an effect equivalent *to 1000* ml of fresh citrate plasma

Clinical Results

The preparation of human antihæmophilic factor has been used with eminently satisfactory results in treating six cases including single and multiple tooth extractions, hæmorrhages into the stomach and joints, and radical surgery of the buttock and rectum

Some details of the cases are given below The effects of transfusion on the level of antihæmophilic factor (A H F) in the patients' plasma are summarised in the accompanying table The mean amount of A H F found in fresh normal *human citrate plasma is 12 5* units per ml (range 8–18) (Wolf 1956)

In the first episode of case 1, presented to us as an emergency, a preparation of A H F having only about half the activity of later ones was infused The initial A H F level in the patient's plasma was as high as 30–40% of normal probably as a result of the massive whole-blood and fresh plasma transfusions which had been given, but despite this he was bleeding into the stomach The bleeding stopped after the infusion of A H F concentrate Of the total A H F units given initially, 40% was found in the blood ten minutes after the completion of the transfusion, a large proportion presumably having been used up in producing hæmostasis *In later tests*, when the patient was convalescent and not bleeding, 83% and 84% of the A H F units injected as concentrate and as fresh plasma respectively, were demonstrable in the blood At this time the patient's plasma-A H F had fallen to a level commonly associated with moderately severe hæmophilia (about 15–20% of normal)

In the second episode of bleeding, about four months later, nearly 60% of the A H F injected was immediately used up

The third episode, when twenty-one roots and two teeth were extracted from his mouth, occurred after experience had been accumulated with other cases described below A preoperative transfusion of 300 ml of concentrate brought the plasma-A H F to 11 0 units per ml, which is close to the mean normal level, and no undue bleeding took place during the operation Next day, after the transfusion of 200 ml of concentrate, the plasma-A H F was 8 4 units per ml Similar daily transfusions were given for two more days to maintain the plasma activity at this level Unfortunately samples taken to establish this point were spoilt by the failure of a –20°C refrigerator From the case report it can be seen *that the treatment* was highly effective The transfusion of one of the batches of A H F concentrate (E F 45) was associated with pain in the back *No* reason was found for this reaction, and subsequent recovery was complete and uneventful, the patient leaving hospital two weeks after the operation

The results in cases 2–4 *corroborate* the efficacy of the concentrate They tend also to confirm the finding that more of the injected antihæmophilic factor disappears in a patient bleeding at the time of transfusion than in a patient treated prophylactically before surgery is undertaken

Major surgery involving highly vascularised tissue was undertaken in case 5, a mild hæmophiliac The transfusions of concentrate were given to cover only the period of the operation and that immediately following subsequent treatment being with whole blood For four *days after the operation there was no* bleeding, but, about twelve hours after the dressings had been removed and the wound repacked, a *ruptured* vessel gave rise to hæmorrhage which necessitated the transfusion of whole blood, subsequent therapy was with stored whole blood to maintain the level of hæmoglobin

In case 6 the healing of the gum after the tooth was extracted was delayed by an infection of the socket, presumably arising from the original abscess Satisfactory hæmostasis was undoubtedly established in the early postoperative period The patient developed urticaria after each injection of the *concentrate*, the idiosyncrasy was confined to this patient, for the three batches concerned *had been administered* to other patients without this complication

Case-reports

Case 1 —A *man, aged 37*, weight 12 st 5 lb Mild hæmophilia, with no serious hæmorrhagic episode since adolescence and no permanent joint lesions Family history of hæmophilia

Episode 1

June, 1956 —Admitted to hospital with severe hæmatemesis Initial treatment consisted of transfusion of whole blood and 2 pints of plasma (frozen when fresh) *daily* After five days the daily 2 pint plasma transfusions were discontinued because the bleeding had stopped and circulatory failure threatened Four days later there were further signs of bleeding *melæna* stools, and a progressive fall in hæmoglobin Treatment 1–2 pints of whole blood and 2 pints of frozen plasma daily *On* the fourth day circulatory failure again threatened On the fifth day 200 ml of concentrate (batch EF 29) was transfused (table, episode 1a) During the following two days 200 ml of EF 29 and 1 pint of whole blood were given daily Since there was no further evidence of bleeding, therapy was discontinued after the second day, and the patient was then making a satisfactory convalescence

A week later, the patient having recovered, an experiment was made to compare the change in A H F level produced by the concentrate and by fresh plasma (table, episodes 1b and c) The A H F level was determined before and after administering 200 ml of concentrate EF 29, and next day similar measurements were made before and after the transfusion of 420 ml of fresh frozen plasma

Plasma volume was estimated on the basis of 76 ml of whole blood per kg body-weight Hæmatocrit during episode of bleeding was 25%, and during convalescence 40% In estimating the plasma volume these values were multiplied by 0 90 to correct for trapped plasma and for non uniform distribution of erythrocytes in the vascular system (Mollison 1956)

Episode 2

Oct 31—Admitted from outpatient department, which he attended for follow up, having been found pale and with symptoms of a recent acute blood loss Hæmoglobin 45%, hæmatocrit 28% Stool contained blood Given 300 ml concentrate EF 39 immediately, followed by 2 pints of fresh blood There was no transfusion reaction

Nov 1—Given 900 ml of fresh frozen plasma In the next four days given a total of 1980 ml of fresh frozen plasma Melæna stools disappeared, and transfusion therapy discontinued Patient made an uninterrupted recovery

Episode 3

Nov 21—Dental extraction Hæmoglobin before operation 60%, hæmatocrit 34% Before operation 300 ml of concentrate EF 43 given intravenously (table, episode 3) No transfusion reaction General anæsthetic given through intratracheal tube Two teeth and twenty one roots were extracted, one root had a medium sized dental cyst at its base, which was curetted Dried human thrombin was introduced into the cavities, which were then lightly packed with sterile alginate wool, and dental splints were then applied No undue hæmorrhage occurred at the operation

Nov 22—No hæmorrhage or oozing, but 200 ml of concentrate EF 45 was given to maintain A H F level Patient complained of pains in back during transfusion

Nov 23—No hæmorrhage or oozing 200 ml of concentrate EF 45 given, and patient again had pain in back during transfusion

Nov 24—No hæmorrhage or oozing Further 200 ml of concentrate EF 45 given Pains in back and chest during transfusion relieved by intravenous pethidine

Nov 25—No hæmorrhage or oozing during day, but oozing from one socket started in evening During night 600 ml of fresh frozen plasma arrested the oozing

Nov 26—Given 600 ml of fresh frozen plasma Dental splints removed, no hæmorrhage or oozing

Nov 27 and 28—No hæmorrhage or oozing but given 600 ml of fresh frozen plasma each day

Nov 29—Packed red cells from two pints of blood given No hæmorrhage or oozing End of transfusion therapy

Dec 4—Patient discharged from hospital

Case 2—A man, aged 41 weight 8 st Previous history of moderately severe hæmophilia, with joints showing chronic hæmorrhagic joint disease Family history of hæmophilia Admitted to hospital for extraction of tooth

Immediately before the extraction he was given a transfusion of concentrate FP 20 (180 ml), and the tooth was extracted under gas and oxygen After the extraction the cavity was packed with 'Oxycel' gauze, and a dental splint was applied, which was removed four days later No bleeding whatsoever took place immediately after the extraction or subsequently up to the patient's discharge seven days later

Laboratory findings—Total blood volume (determined by Dr J H Crookston using chromium labelled red cells) 3650 ml Plasma volume 2260 ml Hæmatocrit 42 5% Hæmoglobin 12 5 g per 100 ml For other data see table

Case 3—A man aged 49 weight 8 st History of severe classical hæmophilia, with multiple and severe chronic hæmorrhagic joint disease Admitted to hospital with spontaneous hæmorrhages into both wrists, muscles of both forearms, and both knee joints, occurring over previous three weeks On admission there were signs of active bleeding into the knee-joints, the pain from which had prevented him from sleeping on the previous three nights

He was given a transfusion of concentrates EF 29 and EF 31, total volume 300 ml After an hour the pain in both knee joints had subsided, and the same night he slept well without sedatives His subsequent recovery was uneventful, and he was discharged from hospital after seven days

Laboratory findings—Blood volume measured as in case 2 with chromium-labelled red cells Hæmatocrit 43 5% Plasma volume 2250 ml (See table)

Case 4—A boy, aged 6, weight 42 lb Family history of hæmophilia Admitted to hospital with injury to left leg hæmorrhage into ankle and knee, calf muscle, and muscle of thigh

After a transfusion of 100 ml of concentrate EF 31 he had a severe rigor lasting twenty minutes Some of the same batch of concentrate had been administered to case 3 without untoward effect A test for pyrogen was negative Considerable clinical improvement followed the transfusion, and there was no further hæmorrhage

Laboratory findings—Plasma volume 1070 ml estimated from weight and hæmatocrit Hæmatocrit 28% Hæmoglobin 61%

Case 5—A man, aged 28, weight 11 st 6 lb Previous history of mild hæmophilia, but no family history Various episodes of bleeding from 1947 onwards In July, 1956, while abroad, he had a purulent discharge from his rectum An incision to drain the abscess led to a persistent discharge of pus into his rectum He was flown to England and admitted to hospital for radical treatment

Oct 11, 1956—Given 300 ml concentrate EF 37 Under general anæsthesia external drainage of the abscess was established A broad tract was cut to the abscess by removing about $2^1/_2$ inches of buttock tissue and part of the superficial anal sphincter There was no undue hæmorrhage during the operation (performed by Mr G A Jemson) No hæmorrhage or further treatment until Oct 15

Oct 15—Given 200 ml of concentrate EF 37 Wound then inspected by surgeon and repacked During the night hæmorrhage occurred and hæmoglobin dropped from 77 to 45% and hæmatocrit fell from 41 to 23%

Oct 16 to 22—Patient received successively 3 pints of stored blood (Oct 16), 2 pints of fresh blood (Oct 17), 2 pints of fresh blood (Oct 19), $2^1/_2$ pints of stored blood (Oct 21), and 2 pints of stored blood (Oct 22) After this no further hæmorrhage took place, and the patient made an uninterrupted recovery, being discharged on Dec 20

Laboratory findings—Plasma volume estimated from weight and hæmatocrit Hæmatocrit before first injection on Oct 11 was 44% (uncorrected) and before second injection on Oct 15 41% (uncorrected)

Case 6—A boy, aged 18, weight 10 st Moderately severe hæmophilia No family history of hæmophilia He had been admitted twenty-four times for episodes of bleeding including hæmorrhages into joints causing limited movement of right knee and left elbow

On Oct 25, 1956, he was admitted for extraction of the first molar in the right lower jaw, which had an underlying abscess Local anæsthetic 280 ml of concentrate FF 41 was given immediately before the extraction and was followed by an urticarial rash Difficult extraction, dental splint applied Oozing from socket for an hour after extraction, and slight oozing during night No further bleeding until evening of Oct 28 On Oct 29 100 ml of EF 31 and 100 ml of FF 39 were given and dental splint was removed Another urticarial rash developed with pruritus Rash was arrested with 50 mg of promethazine Bleeding was arrested for twenty-four hours

After this, intermittent oozing from socket recurred and was controlled by digital pressure and the topical application of thrombin On Nov 8 the socket was packed On Nov 11 a substantial hæmorrhage took place On Nov 12 500 ml of fresh whole blood followed by 500 ml of fresh plasma was given No further hæmorrhage The patient was discharged on Nov 18 The plasma volume (estimated with Evans blue) was 2350 ml

Discussion

A potent preparation of antihæmophilic factor would obviously be of great value, in the management of hæmophiliacs, for preventing the development of permanent joint lesions by the early treatment of young patients; for treatment in spontaneous hæmorrhagic episodes where its prompt administration would reduce the period of disability; and for reducing the risks of major surgery.

Our preliminary tests indicate that the concentrate of human antihæmophilic factor we have prepared may have considerable clinical value. The provision of a concentrate of which 100 ml. is equivalent in activity to 1000 ml. of fresh plasma and which can be made available in a few minutes by the reconstitution of stable freeze-dried material is a substantial advance in the treatment of hæmophilia. We hope to achieve a further 10-fold purification so that the activity of 1000 ml. of fresh plasma could be injected in a volume of 10 ml. To do this without substantial loss in the total activity of the starting material is at present difficult. Meanwhile the potency of the present preparation is high enough to obviate the dangers of circulatory overloading during extensive treatment.

The antihæmophilic activity of some animal plasmas is considerably greater than that of human plasma and consequently animal plasmas might be considered more advantageous for the production of potent antihæmophilic preparations. The purification factor for Bidwell's (1955) bovine preparations is as high as 100–400, compared with 20–25 for our human material. However, the hazard of allergic reactions following the repeated administration of heterologous proteins is a serious restriction in the use of these substances—a restriction which does not apply to material from human plasma. In the literature there are reports of hæmophiliacs becoming resistant to therapy after repeated treatment over long periods even with human plasma and products derived from it; the significance of many of these reports is difficult to assess in the light of our present knowledge of the clotting mechanism. It is worth emphasising in view of this that in case 1, in which repeated infusions of our preparation were given over a period of five months, no resistance to therapy appeared, and laboratory tests at the end of the period did not detect any evidence whatsoever of the development of even traces of a specific circulating anticoagulant.

The problems arising in the fractionation of animal plasma-proteins are simplified because the technique can be directed to the recovery of a single constituent without attempting to conserve the others. In the large-scale fractionation of so valuable a commodity as human plasma such an approach is indefensible; the isolation of any particular constituent must be fitted into an overall scheme of fractionation which ensures a reasonable yield of as many as possible of the other constituents, and the freedom of design is inevitably restricted. Moreover, in view of the relatively low concentration of antihæmophilic factor in human plasma, any fractionation stage which does not lead to a recovery of at least 90% of the initial activity is not acceptable.

The advantages which arise from the use of water-miscible solvents for the fractionation of aqueous protein mixtures are well known, but the enhanced flexibility introduced by the additional variable of solvent concentration and the ease with which an aseptic fractionation technique can be operated are worth emphasis. Even so it is necessary to proceed cautiously, for many proteins may be altered by the presence of solvents, even at low temperatures (0 to −10°C), and so lose their characteristic biological properties. The antihæmophilic factor in our experience is especially susceptible to such influences, though whether the loss in activity which can occur is due to some intrinsic instability or to a secondary modifying effect induced by the action of solvents on other plasma constituents is at present difficult to decide. However, after aseptic isolation and drying from the frozen state the human antihæmophilic preparation loses relatively little activity over several months. In this respect it has some advantage over the animal preparations, which need sterilising after separation. Thus Bidwell (1955) could not use Seitz or Berkefeld filtration for sterilising bovine preparations because of the loss in activity on the filters and had to sterilise by ultraviolet light. Variable and high losses were also encountered when bovine preparations were freeze-dried; this has not happened with our human preparations.

In order to obtain a measure of the problem involved in the management of hæmophiliacs, let it be assumed on the basis of our limited clinical experience that a single crisis in a hæmophiliac might on the average be countered by the injection of an amount of antihæmophilic factor equivalent to that in 2 litres of fresh human plasma. This in its turn represents the plasma derived from about seven blood donations. The total number of hæmophiliacs in the country is probably close to 2000; consequently to provide each with a single injection each year would require 14,000 blood donations. This figure represents about 2% of the current total annual donations. The processing of the plasma from 14,000 blood donations by the procedure found necessary to ensure a maximum recovery of antihæmophilic factor presents a formidable problem, whose solution is not yet clear. These difficulties arise mostly because of the speed with which the processing must be done. We hope that further work may reduce them, but exploratory experiments have already indicated that neither the use of non-wettable surfaces in collecting the blood nor the use of edetic acid ('Sequestrene') in anticoagulant mixtures reduces the rate at which antihæmophilic activity is lost in drawn blood or in plasma.

Summary

A preliminary clinical trial in six cases of hæmophilia indicates that the intravenous injection of a concentrate of human antihæmophilic factor arrests internal and external bleeding, and permits surgical intervention without abnormal bleeding.

The concentrate of human antihæmophilic factor, which contains not less than 85% of the initial activity, is separated aseptically from fresh citrated normal human plasma; the purification factor is 20–25-fold per gramme of protein.

Solutions of the concentrate may be dried from the frozen state without significant loss in activity, and the activity of the freeze-dried material is retained for several months with only slight loss.

The dangers of circulatory overloading during treatment are largely avoided with this preparation, since 100 ml. is equivalent in antihæmophilic activity to 1000 ml. of fresh normal citrate plasma.

Our thanks are due to Dr J. V. Dacie and Dr J. H. Crookston of the Postgraduate Medical School of London, Dr C. Holman of Lewisham Hospital, and Dr K. E. Saunders of Dulwich Hospital for their coöperation and assistance during the clinical trials.

We wish also to thank Mr L. Vallet, B.A., and Miss S. L. Evans, B.SC., of the blood products laboratory, Lister Institute, Elstree, Herts, for undertaking the pilot plant production of the antihæmophilic factor preparations used in the clinical trials; and Dr J. D. James and Dr R. A. Zeitlin for their invaluable coöperation.

One of us (P. W.) is indebted to the Medical Research Council for personal and research grants.

STAPHYLOCOCCAL BRONCHOPNEUMONIA IN DEBILITATED HOSPITAL PATIENTS

A REPORT OF FOURTEEN FATAL CASES

G. A. GRESHAM

UNIVERSITY BACTERIOLOGIST TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE

From the Department of Pathology, University of Cambridge

IN May, 1955, a patient in a male medical ward died unexpectedly while convalescing from coronary thrombosis, and at necropsy death was found to be due to bronchopneumonia. Although a heavy growth of a coagulase-positive *Staphylococcus aureus* was obtained from the lungs of this patient, the histological appearance of the lung lesions differed greatly from those seen in the lungs of patients dying of a staphylococcal pneumonia. Instead of multiple foci of necrosis scattered throughout the lungs, progressing in places to frank abscesses, most of the affected bronchioles and alveolar ducts were intact but surrounded by extensive areas of hæmorrhagic œdema. There was, in fact, a striking resemblance between the microscopical appearance of these lesions and those found in patients with epidemic influenza dying of fulminating secondary staphylococcal bronchopneumonia.

During the following eighteen months the lungs were examined both histologically and bacteriologically in sixty cases in which a pulmonary infection was suspected at necropsy, and thirteen further examples of this type of staphylococcal bronchopneumonia were found; in only four of these thirteen patients had any kind of acute infection of the lungs been suspected during life.

Illustrative Case-reports

Case 1.—A man, aged 76, was admitted to hospital on May 1, 1955, with an attack of severe precordial pain of 24 hours' duration and was treated as a case of coronary thrombosis. Next day, although he was relieved of his pain, his temperature had risen to 102°F, and crepitations were heard at the bases of both lungs. Crystalline penicillin 500,000 I.U. was given 6-hourly together with streptomycin 1 g. 12-hourly, but he became semiconscious and, after repeated attacks of cyanosis of varying degree and duration, he died on the fifth day after admission to hospital.

Necropsy findings.—There was bilateral lower lobe bronchopneumonia with thin pus in the bronchi and bronchioles. Histological examination of the lungs showed acute bronchopneumonia of the lower lobes, with many bronchioles and alveoli full of pus cells and clumps of gram-positive cocci, the surrounding alveoli being filled with red cells and fibrin or œdema fluid. Areas of fibrosis were found in the lateral wall of the left ventricle; the coronary arteries showed severe atheroma but there was no evidence of thrombosis. A heavy growth of *Staph. aureus* was obtained from the lungs.

Case 2.—A man, aged 63, was admitted to hospital on June 9, 1955, with acute retention of urine. His bladder was decompressed, and he was given sulphadimidine 1 g. 8-hourly. 2 days later a transvesical prostatectomy was done, and his immediate postoperative progress was satisfactory. On the 2nd day after operation his temperature rose to 100°F and he was given crystalline penicillin 500,000 I.U. 8-hourly together with streptomycin 0.5 g. 12-hourly for a suspected infection of the urinary tract. A week later his temperature was still raised when he collapsed suddenly with profuse hæmaturia, his blood pressure falling from 220/150 to 100/60 mm. Hg. In spite of the transfusion of three pints of blood he remained in a state of shock and died suddenly 9 days later, immediately after an attack of hyperpnœa. The blood-urea level, 3 days before death, was 331 mg. per 100 ml.

Necropsy findings.—There were areas of recent bronchopneumonia in both lower lobes, and the bronchi contained pale brown pus. Histological examination of the lungs showed areas of bronchopneumonia in the lower lobes, almost amounting in places to abscesses, in which there were many clumps of gram-positive cocci; the alveoli adjacent to these areas were filled with red cells and fibrin. The prostatic cavity appeared to be healing satisfactorily, but the boundary zone of both kidneys was blurred, suggesting distal tubule nephrosis, which was confirmed microscopically. A heavy growth of *Staph. aureus* was obtained from the lungs.

Case 3.—A woman, aged 68, was admitted to hospital on May 14, 1955, with 7 days' history of occipital headache, giddiness, vomiting, and increasing drowsiness. A cerebral tumour or virus encephalitis was diagnosed, and a 10-day course of chloramphenicol 0.5 g. 6-hourly was begun 2 days later. On June 1 a urinary infection was suspected and treated with streptomycin 1 g. 12-hourly and erythromycin 0.2 g. 6-hourly. A non-productive cough began on June 29 and was followed 4 days later by the expectoration of copious amounts of yellow sputum and by cyanosis and coldness of the extremities; the patient died the same day. Radiography shortly before death showed a bronchial carcinoma.

Necropsy findings.—A carcinoma was found arising from a bronchus leading to the left upper lobe, and metastases were present in the hilar lymph-nodes. There was a quantity of pus in the bronchial tree, and areas of bronchopneumonia in both lower lobes contained large clumps of gram-positive cocci. The alveoli surrounding these areas of bronchopneumonia contained many red cells and much fibrin; there were recent thrombi in several pulmonary veins. A metastasis was also found in the right cerebellar hemisphere. *Staph. aureus* was isolated in pure culture from the lungs.

Case 14.—On Nov. 28, 1956, a man fell from his bicycle and was admitted to hospital semiconscious. He had a severe lacerated scalp wound, but no fracture of the skull or abnormality of the central nervous system was discovered. His blood-pressure was 120/80 mm. Hg. He was given sulphadimidine 1 g. 6-hourly, crystalline penicillin 500,000 I.U. 8-hourly, and streptomycin 1 g. 12-hourly. For the next 6 days he remained semiconscious, by the end of which time he had developed flaccid paresis of his right arm. 2 days later his temperature, pulse-rate, and respiration-rate started to rise, and diminished air entry at the base of the right lung was found. Next day he collapsed suddenly with severe cyanosis, dyspnœa, and coldness of the extremities, temperature 105°F, pulse-rate 160, respirations 40 a minute, and blood-pressure 60/? mm. Hg. He died an hour later.

Necropsy findings.—The trachea and main bronchi contained pus in which were large numbers of cocci (fig. 1), and

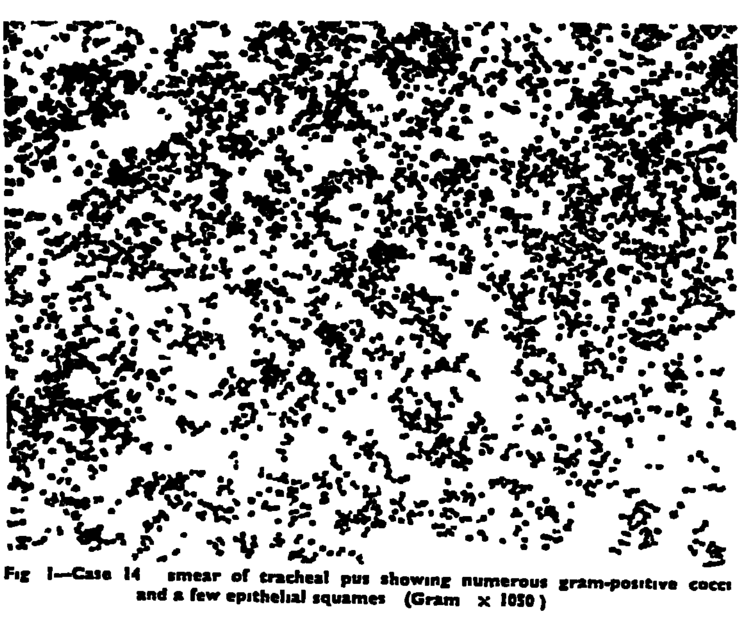

Fig. 1—Case 14: smear of tracheal pus showing numerous gram-positive cocci and a few epithelial squames. (Gram × 1050.)

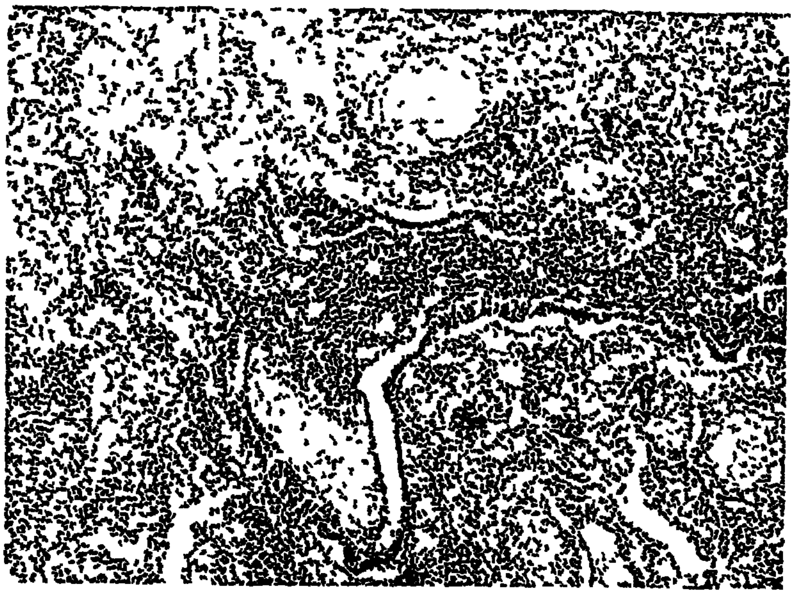

Fig 2—Case 14 section of lower lobe showing bronchiole filled with pus and surrounded by alveoli filled with red cells (Hæmatoxylin and eosin × 65)

areas of bronchopneumonia were seen in both lower lobes The bronchioles were filled with pus and clumps of gram-positive cocci Surrounding alveoli contained hæmorrhagic œdema fluid (fig 2) A heavy growth of *Staph aureus* was obtained from all lobes of the lungs

Post-mortem Findings

Histology

The microscopical appearance of the pneumonic areas in all these cases was similar There were many polymorphs and clumps of gram-positive cocci in the affected bronchioles and alveolar ducts, and the surrounding alveoli were filled with hæmorrhagic œdema fluid (fig 2) In three cases thrombi were found in some of the pulmonary vessels but never in sufficient numbers to explain the hæmorrhagic nature of the œdema fluid More advanced lesions were seen in two cases, an empyema thoracis in case 9, and numerous small abscesses just visible to the naked eye in case 13

Bacteriology

Cultures were obtained from the lungs at necropsy by the simple method of thrusting swabs blindly into the parenchyma of each lobe through small incisions made with a sterile scalpel in the overlying pleura, which had first been carefully sterilised with a branding iron The swabs were plated out on 10% horse blood digest broth-agar and "chocolate" agar, after which the swabs themselves were planted in tubes of Robertson's cooked meat medium All cultures were incubated aerobically overnight, and the amount of growth of the various organisms isolated was roughly estimated and recorded

A heavy growth of *Staph aureus* was obtained from the lungs of eleven of these patients but, in view of the large numbers of gram-positive cocci also seen in sections from the lungs of the three other patients, the poorer growth of staphylococci obtained from them was probably due to the crude method of sampling

Common intestinal organisms were also grown from the lungs of all but two patients The presence of these organisms was thought to imply the agonal inhalation of stomach contents, and they were not regarded as playing any active part in the genesis of the type of bronchopneumonia described here This view is supported by the isolation of intestinal organisms from the lungs at necropsy of forty three out of forty-seven other patients suspected of having a pulmonary infection In eighteen of these there was no histological evidence of any acute infection of the lungs, and only a very low grade bronchopneumonia with no hæmorrhagic œdema was found in the twenty five other patients

The sensitivity of the strains of *Staph aureus* isolated from the lungs of thirteen of the fourteen patients to antibiotics was determined by a simple filter paper strip

BACTERIOLOGICAL FINDINGS

Case no	Sex	Age (yr)	Primary condition	Post mortem lung cultures				Sensitivity to antibiotics of *Staph aureus* isolated from lungs					Chemotherapy in hospital

diffusion plate technique in routine use in this laboratory All strains tested were resistant to penicillin and streptomycin, and all but two to chlortetracycline (aureomycin), conversely, all but two were sensitive to chloramphenicol and all but one to erythromycin These observations are summarised in the accompanying table, which also records the antibiotics received by each patient while in hospital

Discussion

Staphylococcal pneumonia in adults usually runs a severe and protracted clinical course accompanied by much destruction of lung tissue (Chickering and Park 1919) A notable exception to this is the fulminating and often fatal staphylococcal bronchopneumonia that occurs in some cases of epidemic influenza In this type of staphylococcal infection there is little destruction of lung tissue, and death is usually regarded as being due to an overwhelming toxæmia arising from the rapid colonisation of the already infected lungs by inhaled staphylococci

Although there was no evidence that any of the present fourteen patients with staphylococcal bronchopneumonia had influenza in the first place, the histological appearance of the lung lesions was indistinguishable from that described in patients with influenza dying of a secondary staphylococcal infection of the lungs (Wollenman and Finland 1943)

This similarity between the type of staphylococcal pneumonia occurring as a fatal complication in influenza and that found at necropsy in this otherwise unrelated group of hospital inpatients could most easily be explained if there was a predisposing factor common to them all A review of the various conditions for which these patients were being treated in hospital, coupled with a consideration of the changes in the lungs in influenza, suggests that the most likely common factor was the existence of pulmonary œdema at the time of the initial infection of the lungs with staphylococci The presence of a quantity of serous fluid in the alveoli, whether inflammatory or mechanical in origin, would provide, from the outset, favourable conditions for the rapid and widespread colonisation of the lungs by staphylococci and for the subsequent production of toxæmia which are the salient features of this type of pneumonia

The pattern of resistance to penicillin, streptomycin, and chlortetracycline shown by the strains of *Staph aureus* isolated from the lungs of these patients leaves little room for doubt that they were all "hospital" staphylococci (see table) The rapidly increasing pollution of the hospital environment with antibiotic resistant organisms of all kinds (*Lancet* 1956) suggests that this type of staphylococcal pneumonia is likely to become one of the most serious of the cross infection hazards that the debilitated patient has to face in hospital

If this is the correct interpretation of the origin and significance of this condition, a careful reassessment should be made of the value and dangers of oral sprays, the passage of tubes through the nasopharynx, and the use of drugs which depress the cough reflex in the immediate postoperative period or in other conditions in which pulmonary œdema is likely to be present

Early diagnosis is also important because at present the only treatment likely to be successful is the giving of full dosage of the appropriate antibiotic before the number of staphylococci in the lungs has become large enough to produce fatal toxæmia However, in view of the fact that in only four of the present fourteen cases was any kind of acute infection of the lungs suspected during life, early diagnosis is likely to remain infrequent until the possibility of a staphylococcal bronchopneumonia is regularly considered whenever there is unexpected deterioration in the general condition of a debilitated patient

Summary

Staphylococcal bronchopneumonia, similar in type to that which occurs as a fatal complication in influenza, has been found in 14 out of 61 hospital patients suspected of bronchopneumonia at necropsy

In only 4 of these 14 patients had a lung infection been diagnosed during life, none had influenza

These cases are regarded as hospital cross infections Pulmonary œdema may be a predisposing factor

We wish to thank the consultant staff of the United Cambridge Hospitals for access to their case records, Dr. A. M. Barrett for his coöperation in the examination of the necropsy material, and Mr S T Haslam, A I M L T, for his valuable technical assistance

In a previous communication (Martin and Walker 1957) we reported results obtained by measuring, with the long-life isotope ^{22}Na, day-to-day variations in exchangeable body-sodium The results were compared with those obtained by ordinary sodium-balance studies and the two methods were found to be in excellent agreement

We report here results of direct serial measurements of total body-^{22}Na with external counters and compare them with those obtained by the two other methods just mentioned The body counter used was a modification of that described by Bradley et al (1957) using four matching Geiger-Müller tubes (20th Century Electronics type G26) partly shielded with lead, mounted on a trolley, and connected in parallel to a probe unit and thence to a conventional scaler The trolley was low enough to fit under the ordinary hospital bed so that measurements could be made on bed patients

Material and Methods

Serial determinations of total body-^{22}Na, specific activity, and total exchangeable body sodium were made

TABLE I—CLINICAL DATA AND DURATION OF STUDY

Case no	Age (yr)	Sex	Diagnosis	Duration of study (days)	Clinical information
1	23	F	Adrenal virilism	20	Adrenal stimulation and suppression tests
2	47	F	Nephrotic œdema	26	Treatment of œdema with ion-exchange resin and mercurial diuretics

Coefficient of variation	±0 8%

daily on 6 persons (2 men and 4 women), whose clinical details are summarised in table I

2 patients were on a measured intake of food and fluids The intakes of electrolytes and nitrogen were measured by analysis of duplicate diets or, in the case of patients not on a full diet, by analysis of samples of foodstuffs from the same batch as that received by the patients 1 patient was on the standard hospital low salt diet containing about 22 m eq of sodium daily The remaining 3 patients were on the ordinary ward diet

Urine was collected in twenty-four-hour periods starting at 6 A M Spot urine samples for determination of radioactivity were collected in a fasting state at the end of each twenty-four-hour-collection period Fæces were collected over several days, according to the particular study Samples of blood were taken in the fasting state at about 9 A M daily or on alternate days Patients were weighed at a fixed hour each day on a balance accurate to ±50 g

The chemical methods used for analysis of diets, fæces, and urine have been described previously (Martin and Walker 1957)

Radiosodium (^{22}Na) was given orally in doses of about 25 µC The external counter was calibrated for each patient by equating the initial counting-rate, once a constant level had been reached, with the dose given estimated in a liquid sample scintillation counter ('Ekco' type N 550) All counts were corrected for counter dead time Calibration was done in this way in each case because the calibration figure varies from person to person according to the person's size and shape The radioactivity of spot urine, twenty-four-hour urine, and plasma was measured in a liquid sample scintillation counter The radioactivity of each sample was compared with an aliquot of the administered dose, at least 10,000 counts being recorded on each sample By subtracting the amount of tracer excreted in urine and fæces in each twenty four hour period from the amount previously present in the body, the total body ^{22}Na was calculated for each day At the same time the total body ^{22}Na was measured daily with the external counter Serial determinations of total exchangeable body sodium were then obtained independently by measuring specific activity by the dilution principle (Edelman et al 1952) Since corrections for protein content of plasma and the Gibbs-Donnan effect are opposite in direction they were ignored

Results

Performance of Whole body Counter

In the 6 patients, who were of average size and body build, the dose used gave an initial counting rate of 10,000–12,000 counts a minute The background count in the ordinary hospital wards away from artificial radioactive sources was about 700 counts a minute

During the first hour repeated measurements showed minor fluctuations of ±5% Thereafter a steady state was reached (table II)

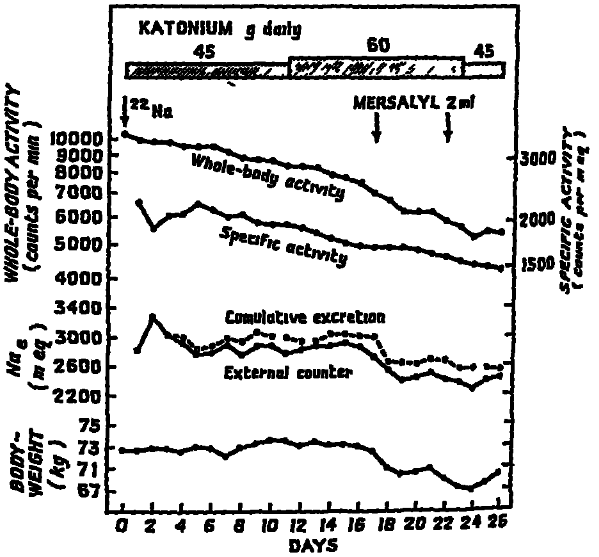

Fig 1—Case 2 (woman aged 47 with nephrotic œdema) total body counts, specific activities, exchangeable body sodium (by both cumulative-excretion and external-counter techniques), and body-weight

All measurements of whole body activity were made in duplicate or triplicate and based on at least 30,000–40,000 counts As was expected from the total counts recorded, the coefficient of variation was 0 5–0 6%

To assess the effect of variation in position of patient and counter, duplicate counts were obtained with the counter placed exactly underneath the patient with one set of counters level with his shoulders The patient was next asked to walk round the bed and lie down again in about the same position as before No attempt was made to adjust either patient or counter In 70 such observations the coefficient of variation was 0 7%, giving an overall error of 0 9% for individual measurements of total body-^{22}Na (table III)

Serial Measurements of Na$_e$

In 5 of the 6 patients the apparent calculated Na$_e$ increased with time over the first 72 hours after ingestion of the dose, and the figure obtained on the third day was accepted as the initial equilibration value The 6th patient had gross œdema due to the nephrotic syndrome, and equilibrium of distribution was not reached until the fifth day after administration of the tracer dose (fig 1) In this case specific activity over the first four days was calculated from spot urine samples Thereafter and in all subsequent cases plasma was used in preference to urine

From the known standard errors of the individual measurements involved, including flame photometer errors and counting errors, the measurement of Na_e was calculated to have a standard error of 2·4%. The accuracy of the Na_e determination based on measurements of total body-^{22}Na with the external counter are well illustrated in fig. 1. The loss of sodium in response to therapy was due to the decrease of œdema fluid accurately reflected in the change in body-weight. The daily Na_e measurements followed the alterations in body-weight so closely that the curves were almost parallel.

Comparison of Isotope Methods

Serial measurements of Na_e by the cumulative-excretion method and by the external-counter technique in the 6 patients are shown and compared in table IV and figs. 1–3. Although the agreement between the two methods is within their confidence limits, the cumulative-excretion method showed a greater gain or smaller loss than did the external-counter method in 5 of the 6 cases studied. This is further reflected in the tracer's calculated biological half-life shown in table V.

Comparison of Isotope and Metabolic-balance Data

The isotope and metabolic-balance data in 2 patients (cases 1 and 3) are compared in table IV and figs. 2 and 3. In both cases the agreement is within the confidence limit of the isotope techniques of ±50 m.eq.

Discussion

The patients formed a heterogeneous group chosen because of anticipated changes in sodium metabolism. Since we were mainly interested in comparing two methods of study under the widest range of conditions, this heterogeneity was an advantage.

The measurement of exchangeable sodium was found to have an error of 2·4%, in keeping with the degree of reproducibility shown by Veall et al. (1955) using eight instead of four Geiger-Müller tubes. These workers, however, suggested that repeated measurements made on the same subject showed a considerably wider variation —in most cases about 5% or more. Such wide variations may be explained by changes in the specific activities of urine used for calculating Na_e, because their paired measurements were made at 11 A.M. and 2 P.M., not in a fasting state, and with the midday meal intervening. The variability suggested by Veall et al. (1955) cannot therefore be accepted as being a true indication of the confidence limit of the method. To exclude errors due to fluctuations in specific activity of urine, specific activity of fasting plasma was used in the present investigation for calculating total exchangeable body-sodium except where otherwise stated.

The slow increase in Na_e over the first three to five days observed on previous occasions (Burch et al. 1952, Miller et al. 1954, Veall et al. 1955, Martin and Walker

TABLE IV—COMPARISON OF ISOTOPE AND METABOLIC-BALANCE DATA

Case no.	Duration of comparison of balances (days)	Na_e (m.eq.) Initial	Na_e (m.eq.) Final	Change in Na_e (m.eq.)	Metabolic balance change (m.eq.)	Difference (m.eq.)
1	17	1930* 1970	1950* 2160	− 20* −190	−57	37* 133
2	23	3040* 3040	2420* 2540	−620* −500		120

TABLE V—BIOLOGICAL HALF-LIFE BASED ON URINARY AND FÆCAL SODIUM LOSS COMPARED WITH THAT OBTAINED DIRECTLY BY EXTERNAL COUNTING

Case no	Biological half-life (days)		Difference
	Cum ^{22}Na method	Ext counter	
1	18	17	1
2	30	28	2
3	25	25	0
4	35	31	4
5	25	20	5
6	34 Unmeasured losses	22	12

1957) was confirmed and is consistent with the view that some of the ^{22}Na is associated with a separate and more slowly exchanging compartment of body-sodium, which is believed to be sodium in bone (Miller et al 1954)

In considering the comparisons between the two isotope methods certain orders of variability must be borne in mind The accuracy of individual measurements of Na$_e$ is ±2 5%, hence the differences observed were still within the confidence limits of the two methods Case 6 must be excluded from the comparison because unmeasured losses rendered the cumulative excretion data invalid In 4 of the remaining 5 comparisons the cumulative-excretion balance indicated a greater gain or a smaller loss than did the external counter method In the 5th patient (case 3) the counter recorded a smaller loss, but the discrepancy was small The difference in the two methods is also expressed in the calculated biological half life, which was in 5 cases out of 6 shorter when estimated directly on total body-^{22}Na It is tempting to suggest that the differences observed indicate loss of sodium in sweat This would amount to a daily loss of 1–8 m eq of sodium in sweat Case 1, who lost the greatest amount of sodium in sweat, was allowed to leave the hospital for afternoons and may well have perspired at times in addition to insensible loss Such figures as are suggested for loss of sodium in sweat are compatible with the finding of Freyberg and Grant (1937) that people lightly clad and doing light laboratory work without visible sweating lost 2 6–9 1 m eq of sodium a day

The metabolic balance data obtained in 2 patients compare favourably with those obtained by the isotope techniques and confirm our previous findings (Martin and Walker 1957) The reproducibility and accuracy of the metabolic-balance method cannot be ascertained experimentally but are probably less than those of the isotope techniques, probably because of the variability of diet rather than unmeasured losses, although the latter may also contribute Unmeasured losses will, however, affect the cumulative excretion method, as in case 6, and are only eliminated by the external counter technique Whole-body activity after section of the pituitary stalk decreased in case 3 (fig 3) and, to a lesser extent, in case 6 out of proportion to the amount of tracer lost from the body When cortisone was given, whole-body activity increased again, the increment being outside the limits of experimental error Since neither patient had received further radioactive material, the behaviour of the external counter suggests redistribution of sodium within the body, with a lower counting-rate Sodium is known to be redistributed in acute adrenal insufficiency, and the observation made may perhaps be explained by a movement of sodium from the extracellular space into bone, an area of low sensitivity of the external counter, with self-absorption playing an additional rôle Further work is obviously required to investigate this point and to clarify the relationship of distribution of sodium reflected by the tracer and recorded by the external counter

The results obtained support the view that, with ^{22}Na, the external counter affords a method of unprecedented ease and accuracy for studying sodium metabolism Neither dietitian, diet kitchen, nor metabolic unit is required, and, once the isotope has equilibrated with the stable sodium available for exchange, results of daily gains or losses can be made known within a matter of minutes to the physician or surgeon in charge of a case The reproducibility and accuracy of the method can be assessed Cumulative errors are eliminated by directly measuring the total body content of tracer In fact the metabolism of sodium can be studied in outpatients because the complete collection of all excreta is unnecessary and the loss of sodium in sweat need not be considered

The long half life (2 6 years) of ^{22}Na may give rise to some misgivings about the radiation dose received by the patients, but the biological half life has been shown to depend on the intake of sodium as well as on the state of the sodium balance (Martin and Walker 1957), and excretion of the isotope can readily be hastened by a high intake of sodium There is no evidence of permanent retention (Veall et al 1955) The radiation hazard involved with the doses used is small, being only about half that of the permissible body burden of ^{22}Na

Summary

The total body-^{22}Na was measured directly with external Geiger Müller counters, and, by measuring specific activity, exchangeable body sodium was calculated for each day

The standard error for whole-body radioactivity was ±0 9% and for total exchangeable body sodium ±2 4%

Daily comparisons were made with the cumulative excretion method in which total body-^{22}Na was calculated by subtracting successive twenty-four hour losses, and with chemical metabolic-balance data The methods were found to be in good agreement Although the differences were small they could be explained by loss of sodium in sweat

The external counter offers a simple and accurate method for studying sodium metabolism without either collecting excreta or measuring dietary intake

We wish to thank Dr J D N Nabarro for much advice and encouragement, and permission to study cases under his care, Dr Arthur Willcox for permission to study case 5, Prof J E Roberts for facilities in the Barnato Joel Institute, and the Leverhulme Trustees for a scholarship granted to one of us (M M M)

"Contemporary physicists have abandoned some old intuitions about the nature of the physical world They have, for instance, renounced the concept of the permanence of objects in the submicroscopic realm a particle does not exist unless it can be localized, if it cannot be located at a particular position, it loses its title as an object and must be described in other terms Now by an extremely curious coincidence it is found that a very young baby acts with regard to objects rather like a physicist The baby believes in an object as long as he can localize it, and ceases to believe in it when he can no longer do so The great difference between the baby and the physicist, of course, is that the baby's faculty of localization is less powerful"—JEAN PIAGET, *Sci Amer* March, 1957, p 46

COMPARISON OF GASTRIC EMPTYING AND SECRETION IN MEN AND WOMEN

WITH REFERENCE TO PREVALENCE OF DUODENAL ULCER IN EACH SEX

ANY difference which there may be between the gastric emptying and secretion of men and of women might be expected to have some bearing on the prevalence of duodenal ulcer in the two sexes The present paper is intended to supplement by new methods the previous comparisons of gastric activity of men and women in the hope of throwing light on the causes of duodenal ulcer

Methods

The rate of emptying of a meal from the stomach depends in the main on two variables, the propulsive power of the stomach, and the effectiveness of the inhibitory mechanisms which normally check the emptying of the stomach The receptors whose activity slows gastric emptying lie mainly in the walls of the duodenum and upper part of the small intestine, hence they are exposed to stimulation by the material leaving the stomach For example, when the gastric effluent has a high osmotic pressure or when it contains fat, gastric emptying is slowed (Shay 1944) Once it is appreciated that the rate of emptying depends on a balance between the action of the gastric propulsive mechanism and the action of the inhibitory mechanism in the duodenum, comparisons of the gastric emptying of different individuals can be framed in terms of two questions

(1) How powerful is the gastroduodenal pump when it is not inhibited ?

(2) How effective is the inhibitory mechanism ?

Thus, for example, rapid gastric emptying might occur either with a very powerful stomach opposed by a normal duodenal brake or with a normally powerful stomach opposed by a very weak brake

Earlier experiments have shown that saline test-meals containing 100 m eq of sodium chloride per litre leave the stomach very quickly, presumably because such meals activate the duodenal brake only to a small extent (Hunt 1956) Thus the emptying-rate of a saline meal gives a tentative index of the uninhibited emptying power of the stomach On the other hand, a meal of distilled water of equal volume operates the duodenal brake and leaves the stomach at about half the rate of the saline meal Thus by comparing the emptying-rates of equal volumes of saline and water an index of the activity of the duodenal brake may be obtained

The test-meals used in this work were mainly designed to investigate gastric emptying but also allowed the assessment of the amounts of acid, chloride, and pepsin secreted in response to the meals

Technique—The subjects, who were all volunteers, were students in the medical school or in the school of physiotherapy They came fasting to the laboratory at about 8 A M To standardise the influence of the menstrual cycle on gastric emptying and secretion the women were all tested within the first seven days after the end of their menses (MacDonald 1956) After the stomach has been washed out with 250 ml of water through a tube the subjects were given a test-meal of 750 ml of water or of saline solution (100 m eq of sodium chloride per litre) at 37°C through the tube Nine minutes after the saline solution or nineteen minutes after the water meal the gastric contents were recovered through the tube Any residue was aspirated separately after a further 250 ml of tap water had been given The test meals contained phenol-red as a marker From the amount of this material recovered it is possible to calculate the volume of the gastric contents which have left the stomach From the amounts of the secretion recovered plus those calculated to have left the stomach the total amounts of acid, chloride, and pepsin secreted can be assessed The methods have been described in full (Hunt 1954)

Results

Gastric Emptying of Saline Meals and Meals of Water

The mean volumes of the gastric contents and of the original meal remaining were much the same in the twenty men and nineteen women both for the saline solution and for the water, as may be seen from the accompanying table, which also shows that the mean volume of saline meal remaining at the end of ten minutes was only slightly greater than the mean volume of the meal of water remaining after twenty minutes The data for the women were more variable than those for the men

The same data may be examined in more detail in fig 1, in which the volumes of the meal remaining after saline solution and after water have been plotted for each person Since the points fall around a straight line, it follows that those persons who emptied the saline solution rapidly also emptied the water rapidly Moreover the relationship between the two volumes is the same for the men and the women

Gastric Secretion in Response to Saline Solution and Water

The table shows that the men secreted about one and a half times as much acid as did the women in response to both saline solution and water It also shows that, both for the men and the women, the secretion of

MEAN DATA ON GASTRIC EMPTYING AND SECRETION IN MEN AND WOMEN IN RESPONSE TO MEALS OF SALINE SOLUTION AND WATER

—	Saline solution (10 min)		Water (20 min)	
	Men	Women	Men	Women
Volume of gastric contents (ml)	454 (±26)	453 (±32)	380 (±23)	398 (±31)
Volume of meal remaining (ml)	393 (±20)	393 (±30)	327 (±21)	344 (±27)
Output of acid (m eq)	2·21 (±0·37)	1·48 (±0·21)	5·22 (±0·70)	3·21 (±0·36)
Output of chloride (m eq)			8·58 (±0·72)	6·58 (±0·53)
Output of pepsin (units)	3610 (±440)	2420 (±290)	5850 (±480)	2850 (±290)
Concentration of acid in gastric contents (m eq per litre)	3·3 (±0·45)	2·3 (±0·33)	8·2 (±0·75)	5·4 (±0·67)

Figures in parentheses are standard errors of means

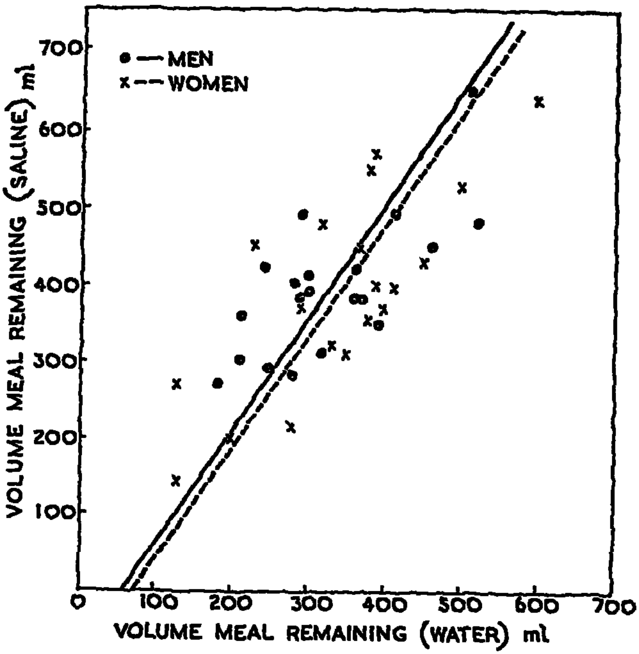

Fig 1—Volume of test-meal remaining after meals of water (20 min) and of saline solution (10 min)

acid was slightly more than twice as great for the twenty-minute test with the water as it was in the ten-minute test with the saline solution The secretion of chloride in response to water was greater in the men than in the women The secretion of chloride in response to meals of saline solution cannot be accurately determined by this method, because it is sensitive to errors in assessing the amount of chloride leaving the stomach with the gastric contents When the concentration of chloride in the meal is 100 m eq per litre, these errors dominate the small secretion of chloride which occurs in the ten-minute digestive period allotted to the saline solution

In response to both meals the men secreted more pepsin than did the women The men secreted more pepsin in the twenty-minute digestive period with water than they did in the ten minute period with the saline meal, but this difference does not appear in the data for the women

Discussion

Gastric Emptying

The present data indicate that test-meals of water and of saline solution leave the stomachs of men and women at much the same rate The meals are relatively larger for the women than they are for the men because the women are smaller than the men, but this does not seem to have any bearing on these data, for there is no correlation between body-weight and gastric emptying in either the men or the women, although the weights extend over a considerable range in both groups

Fig 1 shows that those who empty saline solution quickly also empty water quickly, which fact suggests that intersubject differences of the gastric emptying-rates for water are mainly determined by the gastric propulsive power which has been assessed from the emptying-rate of the saline solution Had the differences between subjects in the emptying-rates of water been mainly decided by the varying power of the duodenal brake, there would have been little correlation between the emptying-rates of the two meals From the present findings it can be inferred that the propulsive powers of the stomach and the effectiveness of the duodenal inhibitory mechanisms were equal in the two sexes

The data for women refer only to the second week of the menstrual cycle, for MacDonald (1956) has shown that there is a sudden small increase in the rate of emptying of test-meals at about the time of ovulation

The present experiments did not disclose any large differences between the gastric emptying of normal men and women which might explain the greater prevalence of duodenal ulcer in men Since it has proved impossible to demonstrate any difference between the gastric emptying of normal men and men with duodenal ulcers (Hunt 1957a and b), it may reasonably be assumed that women with duodenal ulcers do not empty test meals differently from normal women If a generalisation from these data is permissible, it seems likely that abnormalities of gastric propulsive power and of its regulation by osmotic factors in meals play no part in the pathogenesis of duodenal ulcer

Gastric Secretion

It is known from the work of Vanzant et al (193') that the acidity of the gastric contents after a test meal is higher in men than in women, a finding which was confirmed in the present investigation This difference is wholly explained by the higher secretory response of the men Because there was in these data no correlation between body-weight and the secretion of pepsin, acid, or chloride either in the men or women, the differences between the secretory responses of men and women to a standard meal cannot be attributed to differences in body-weight

Pathogenesis of Duodenal Ulcers

Although the greater gastric secretion in men might be held to explain the greater prevalence of duodenal ulcer in men, it might also be supposed that duodenal ulceration is the result of a defective resistance on the part of the duodenal mucosa It is therefore possible that duodenal ulcer is more prevalent in men because men more commonly have a defective duodenal mucosa If this were generally true, it would be expected that some men would develop duodenal ulcers at levels of secretion lower than those found in women with duodenal ulcer This hypothesis can be tested by the published data of Ihre (1947), which have been redrawn in fig 2 The ordinate shows the frequency in men and women with duodenal ulcer of the particular levels of gastric secretion in response to histamine marked on the abscissa It is clear that among men and women with duodenal ulcer the lower levels of gastric secretion are equally common The lower prevalence of duodenal ulcer among women can presumably be explained on the basis that fewer women than men attain to the levels of hypersecretion associated with duodenal ulcer

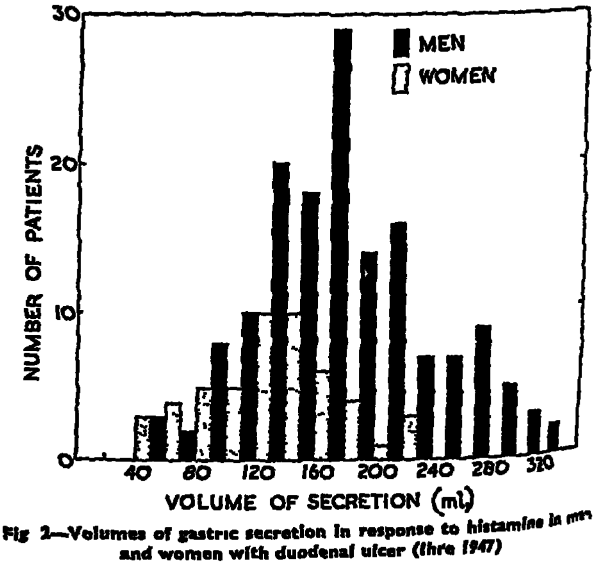

Fig 2—Volumes of gastric secretion in response to histamine in men and women with duodenal ulcer (Ihre 1947)

Conclusions

If the findings in this study are applicable generally, they may be taken to imply that the difference in prevalence of duodenal ulcer in men and women does not depend on any differences between men and women in gastric emptying, but it may depend on differences between men and women in their gastric secretion of acid and pepsin No evidence was found that among patients with duodenal ulcer defective tissue resistance is more common in men than women

Summary

Gastric emptying and secretion were compared in 20 young men and 19 young women

Test meals of saline solution were given to assess the gastric emptying power

Test-meals of water were given to assess the effectiveness of the duodenal osmoreceptors which slow gastric emptying

No difference was shown between the gastric emptying of the men and the women

The secretion of acid, chloride, and pepsin was about one and a half times greater in men than in women

It is tentatively concluded that the different prevalence of duodenal ulcer in men and women does not depend on differences in gastric emptying It might depend on differences in secretion

A consideration of Ihre's (1947) data suggests that differences in tissue resistance do not explain the different prevalence of duodenal ulcer in the two sexes

We are indebted to the volunteers for their coöperation and to the Worshipful Society of Apothecaries for the award to one of us (J N H) of the Gillson scholarship out of which part of the expenses were defrayed

The nature of the closing mechanism between stomach and œsophagus is still a matter of considerable dispute Numerous methods of study have been used, amongst the latest being cineradiography (Nemours Auguste 1951) and manometry (Kramer and Ingelfinger 1951, Dornhorst et al 1954, Fyke et al 1956) In the study recorded here these methods have been combined

Methods

Investigations were carried out on 20 adult volunteers One group consisted of 11 normal medical students, average age about 21 , 3 were women and 8 men A second group, aged 24 to 57, consisted of 7 patients (6 men and 1 woman) in whom at laparotomy at least two months previously a metal clip to act as a radio-opaque marker had been firmly attached to the anterior aspect of the œsophageal hiatus of the diagram Operative examination of the gastro-œsophageal region in all 7 had shown no abnormality , 6 had had partial gastrectomy for peptic ulceration and 1 an appendicectomy In addition, a man in whom a near-total gastrectomy had been performed and a medical student who subsequently proved to have a hiatus hernia were studied

Apparatus

Pressures were measured with an electro manometer of the capacitance type (N E P Ltd) and a two channel direct writing pen recorder (Sanborn 'Twin-viso Cardiette ')

The œsophageal tubes were 'Polythene,' external diameter 2 5 mm Two types were used One had at its lower end a small balloon of thin latex, 1 cm long and 1–1 5 ml in capacity , there were radio opaque markers immediately above and below the balloon to indicate its position The second type was an open tube, with the hole either at the end or on the side and a radio opaque marker to indicate its situation

For cineradiography with image intensification and intermittent radiation, the method for cine-angiocardiography (Astley 1955, Astley and Oldham 1956) was used Each cine frame was exposed as an individual high-speed radiograph, using an exposure of 0 01 to 0 005 sec Thus movement blurring was eliminated The precise instant of each picture was indicated below the pressure-tracing on the second channel of the pen recorder Most examinations were carried out at 16 frames per second, a few at 32

Procedure

Local nasopharyngeal anæsthesia was induced with a few drops of 4% lignocaine, which the subject was instructed not to swallow A tube was passed through the nose into the stomach and the subject placed in the supine position If a balloon-ended tube was being used, it was now attached to the manometer and completely emptied and the balloon inflated the volume of air used was that required to inflate it to atmospheric pressure, as previously determined outside the body To prevent errors from possible leakage, this procedure was repeated at intervals during the examination When open tubes were used, they were attached to the manometer, filled with water, and flushed through after every recording

The subject was turned slightly into the left posterior oblique position to project the lower œsophagus just to the left of the spine and to demonstrate the level of the diaphragm clearly By fluoroscopy the marker at the end of the tube was adjusted to lie well within the stomach The subject, fully relaxed, was instructed to breathe quietly, without swallowing The tube was smoothly withdrawn at a uniform rate until the marker lay a few inches above the diaphragm , on an average, two to four seconds were taken over the withdrawal During this period simultaneous pressure and cineradiographic recordings were taken, the instant of each frame being indicated on the pressure tracing The procedure was repeated several times on each subject, keeping well within safe levels of irradiation Such gastro œsophageal withdrawal curves were also obtained during inspiration and expiration, and many of the subjects were examined by both the balloon and the water-filled open-tube systems As a routine, additional pressure tracings without cineradiographs were also obtained, using various

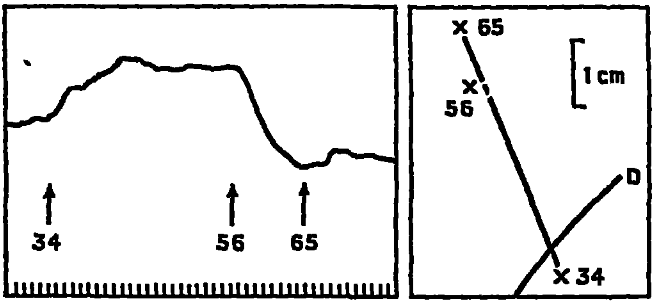
(A) Each cine frame corresponds to a known point on the gastro œsophageal withdrawal pressure curve The upper end of the radio opaque marker indicates the recording hole (arrows) and shows its position relative to the hiatal clip, the diaphragm, and barium in the fundus



(B) From each recording a composite tracing is made at a known degree of magnification, to indicate the anatomical position of salient points on the pressure curve

Fig 1—Method of analysis of recordings

recording speeds and varying rates of withdrawal At the end of the examination barium was given to localise the gastric fundus, and further combined radiographic and manometric recordings made

Tracings during which there was inadvertent swallowing were discarded, and at least ten seconds were allowed to elapse after a swallow before recording

To exclude artefacts due to a closed glottis and the action of the accessory muscles of respiration, tracings made during inspiration were recorded towards the end of the movement and not with the subject holding his breath

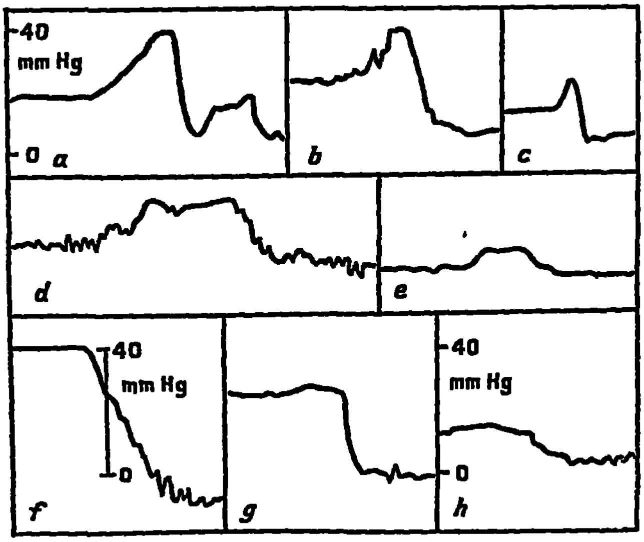


Fig 2—Types of withdrawal pressure-curve

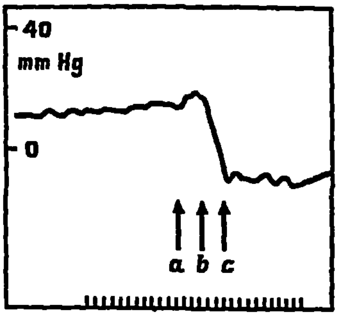
a, b, c saw tooth type *d, e* plateau type *f, g, h* "step" type *a d* and *f* were obtained from the same subject



Analysis

The cine films were projected frame by frame through a prism on to a horizontal surface As the lengths of the radio opaque markers in the œsophageal tubes were known, it was possible to correct for varying degrees of radiographic magnification by adjusting the projector distance to obtain an image of true life size or of a known degree of magnification In actual practice twice life size proved convenient

The indication of the moment of each exposure on the recording meant that each cine frame corresponded to a given point on the pressure curve The films were projected frame by frame and composite tracings were made of each recording to show the site of salient points of the withdrawal curve relative to diaphragm, hiatal clip, and barium in the gastric fundus (fig 1)

Results

In the 18 normal subjects (i e , excluding the man with the virtual total gastrectomy and the student who proved to have a hiatus hernia), 227 gastro œsophageal withdrawal pressure-curves were obtained 133 were recorded with the open system and 94 with the small balloon There was combined cineradiographic localisation in 129

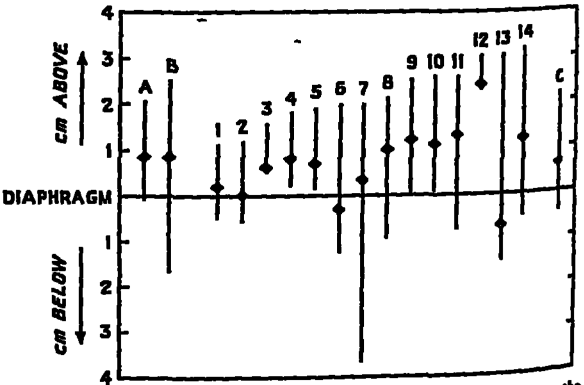


Fig 3—Average positions of the pressure-changes relative to the diaphragm (represented as in fig 4)

A is the mean of individual averages of 10 normal subjects examined with an open tube B is the mean of individual averages of the same 10 subjects examined with the small balloon 1 to 14 are the individual averages of 14 patients examined with an open tube C is the mean of 1 to 14

Types of Curve

The withdrawal curves were of three main types though these merged one with the other In a majority (64%) the pressure curve had a "saw-tooth" shape, with a rise preceding the fall to general intrathoracic level (fig 2, *a*, *b*, and *c*) Another 11% had an initial rise in pressure that assumed a plateau shape (fig 2, *d* and *e*) In the remaining 25% there was no initial rise and the withdrawal curve formed a step (fig 2, *f*, *g*, and *h*)

The type of curve depended to a certain extent on the method of recording With the small balloon a curve containing a pressure rise (either "saw tooth" or plateau) was always obtained With an open system, there was a pressure rise in 54% and a step in 46% Whether the recording hole was at the end or at the side of the tube did not influence results In a given subject there were often variations in the type of curve for which there was no obvious explanation

Site of Pressure Changes

In 10 subjects who were examined with both the small balloon and the open tube, a comparison of average results (fig 3, A and B) *shows that the descent to general* intrathoracic pressure began at the same point, whichever method of recording was used However, the gastro-œsophageal pressure changes as recorded with the small balloon took place over a longer segment, with the increase mainly in the phase of rising pressure This may be attributed to the size of the balloon, and to exclude such errors further description is confined to the results obtained with the open system

The exact situation of the pressure-changes varied from recording to recording in a given subject (fig 4)

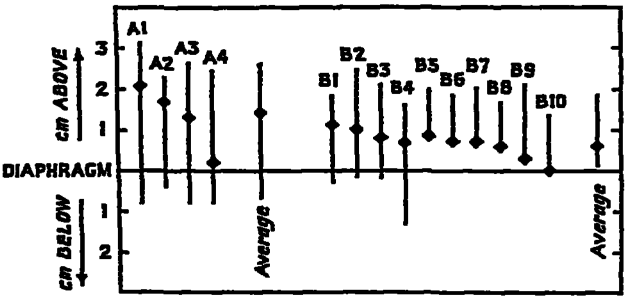

Fig 4—Situation of the gastro-œsophageal pressure changes in 2 subjects

The lowest point of each vertical line indicates the site where the pressure rise begins, the diamond shows the point at which the pressure descent begins, the upper limit is the site at which general intrathoracic pressure is reached A 1–4 are four separate open tube recordings in 1 subject, with their average, B 1–10 are separate recordings and the average in a 2nd subject

---

The average results obtained in 14 normal subjects, and the mean of these averages, are shown in fig 3 In 2 the curves were always of the " step " type In the remaining 12 there was an initial rise in pressure This began above the diaphragm in 4 and below it in 8, with a mean position of 0 45 cm below In 11 of the 12 subjects the position of the gastro-œsophageal junction was shown by barium, the pressure rise commenced above this level in 6

The site at which the descent to general intrathoracic pressure began was above the diaphragm in 11 of the 14, with a mean position for the entire group of 0 65 cm above the diaphragm *The site at which general intrathoracic pressure was reached was in all cases above the diaphragm, with a mean position of 2 15 cm above* The total length of the segment over which these pressure-changes were seen varied from 0 5 to 5 65 cm, with a mean of 2 6 cm

In 6 subjects it was possible to relate the pressure-change as recorded by the open system to the level of the hiatus, which was indicated by a radio-opaque clip (fig 5) The level of the clip did not necessarily correspond to that of the diaphragm and the difference varied with the phase of respiration ; on inspiration th diaphragm descended more than the clip The averag position of the latter was above the diaphragm in subjects and below in 4, although the mean for th group showed a close correspondence of the levels of cli and diaphragm In 4 of the 6 subjects the site at whic the descent to general intrathoracic pressure began wa above the hiatus, with a mean position for the group o 0 3 cm above the clip (A similar observation was mad in a 7th normal subject who was examined only wit the small balloon)

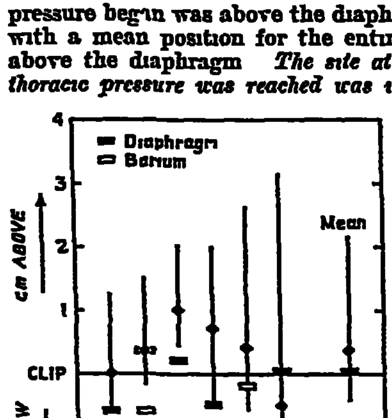

Fig 5—Average positions of the pressure-changes relative to the hiatus (represented as in fig 4)

The level of the hiatal clips is taken as the baseline Individual averages of 6 subjects, examined with an open tube, and their collective mean

Effect of Respiration

There was no obvious or constant relationship betwee the type of the withdrawal curve and the phase o respiration With full inspiration there was an increase difference between the gastric and intrathoracic pressures but the height of the rising phase (whether measure relative to the gastric pressure or as an absolute value showed no constant increase In some recordings it wa slightly higher, in others equivocal, and in a few lower

The length of the segment over which the pressur changes took place tended to be shorter during inspiration, and the point at which the descent to genera intrathoracic pressure began tended to be lower i position But this was not invariably so and the revers was sometimes seen

Miscellaneous Observations

In 1 of the normal students the recording tube was slowly pulled up and down for a few centimetres over the gastro-œsophageal junction, in other tracings the tube was lef stationary with its hole at this level and the same relativ movement obtained by breathing in and out In this subjec the recordings tended to show a three stage pressure change

One student, as already mentioned, proved to have a hiatus hernia The first suspicion of this was the obtaining of bifid tracings of an unusual type during some (but not all) withdrawals Tube movements caused slight reflux of the barium Close questioning elicited a suggestive history and a barium swallow confirmed the hernia.

In the subject who had undergone near-total gastrectomy, lack of symptoms and a barium meal examination indicated normal gastro œsophageal competence Normal types of withdrawal curve were obtained, but the point of maximum pressure rise was very low relative to the diaphragm

Discussion

Two features of the recordings are of particula interest · first, the positive pressure rise above that in the stomach found in 12 of 14 subjects and in over hal the curves obtained ; secondly, the appreciable length o the segment over which the pressure changes occurred —i.e , 0 5–5 6 cm (average 2 6 cm) This second finding is at variance with that of Dornhorst et al (1954) who concluded from manometric studies that functionally the cardia is a localised region extending over not more than 5 mm They considered the behaviour of the mechanism at the cardia to be unlike that of known muscle sphincters and favoured the existence of some form of flap or funnel valve

Our results suggest a mechanism operating in the lower segment of the œsophagus which is producing a compressing effect and therefore unlikely to be purely valvular. The fact that the recorded pressure changes varied in both degree and situation in any one individual indicates that, whatever the mechanism, this too must vary in both its compressing effect and in its exact situation relative to the diaphragm

There are two possible explanations of the compressing effect—an extrinsic one (i e , the crural " pinchcock ") or an intrinsic sphincteric mechanism The compression seems unlikely to be related to crural action since the positive deflection was not constantly increased with full inspiration—i e , when crural action would be expected to be at its maximum Moreover, in subjects who had a radio opaque clip indicating the anterior border of the hiatus, the point at which the fall to intrathoracic pressure began, which was usually also the point of *maximum* pressure, lay above the hiatus in 4 out of 6 subjects It could be argued that crural action extends above the level of the anterior border of the hiatus, but this seems unlikely since the crura slope upwards and forwards from their spinal origin

If the extrinsic factor is dismissed as unlikely to account for the pressure changes, it must be concluded that an important intrinsic sphincteric mechanism exists at the lower end of the œsophagus In the normal subject this may well be the most important component of the gastro œsophageal closure mechanism, though its existence does not exclude the possibility (indeed, *probability*, especially in the abnormal subject) that other factors play a part

Summary

Simultaneous cineradiographic recordings and gastro-œsophageal withdrawal pressure-tracings were made in 18 normal subjects Composite tracings to a known scale showed the site of salient points of the withdrawal pressure curve relative to the diaphragm, the hiatus (as indicated by a surgical clip), and the gastric fundus

The form and situation of the pressure changes varied from person to person and from time to time in a given subject They were seen over a segment averaging 2 6 cm in length In a majority there was a rise to a pressure above that of the stomach preceding the fall to intrathoracic pressure, this rise was not constantly increased during inspiration

The site at which the descent to intrathoracic pressure began was often above both diaphragm and hiatus (the levels of which were not necessarily identical) The site at which intrathoracic pressure was reached was always above the diaphragm

It is concluded that in the normal subject an important component of the closing mechanism is a sphincteric action operating at the lower end of the œsophagus

Grateful thanks are due to the subjects of our study We are indebted to Prof F A R Stammers and Prof J M Smellie for their encouragement, and to the endowment research fund of the United Birmingham Hospitals for a grant

RADIOLOGICAL LOCALISATION OF THE DIAPHRAGMATIC HIATUS

G S Muller Botha
M B Cape Town, F R C S, F R F P S
LECTURER IN SURGERY, UNIVERSITY OF BIRMINGHAM

It has generally been accepted that the diaphragm, as seen in an anteroposterior radiograph, coincides with the level of the œsophageal hiatus The study recorded here was carried out to test the accuracy of this radiological concept by marking the hiatus with a metal clip at operation and examining it postoperatively in relation to the diaphragm

20 suitable volunteer patients of average build were examined (7 women, 13 men) The ages varied from 27 to 63 (average 43) Most of these patients had either a partial gastrectomy or a cholecystectomy Only those were selected who had benign lesions, who were in a good general condition, and who were found at laparotomy to have normal anatomy around the gastro œsophageal junction

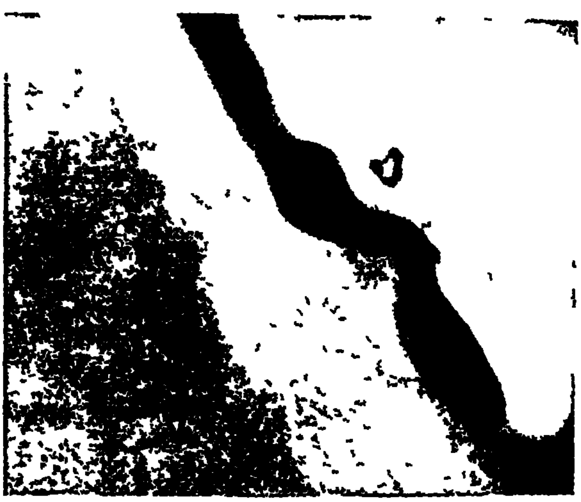

Fig 1—Right oblique, erect posture the clip lies above the line of the diaphragm but below the phrenic ampulla

Method

At laparotomy the hiatal area was carefully examined The left lobe of the liver was mobilised and reflected so that the anterior hiatal margin could be adequately visualised A metal clip was then firmly and accurately attached to the anterior edge of the diaphragmatic hiatus immediately in front of the œsophagus Each patient had a radiological examination within two and a half months of the operation Some patients had several investigations Radiographs were taken in various postures and during different phases of respiration When it was necessary to compare these pictures, the same position was ensured as far as possible by overlapping skin markers on each side of the body The relationship of the clip to the œsophagus was demonstrated by barium swallow and by a 0 8 × 18 cm balloon containing a radio opaque contrast medium that was passed down the œsophagus to the gastro œsophageal junction

Results

The comparison of radiographs is notoriously difficult, especially when taken in different postures and phases of respiration

Position of the Clip at Rest

Erect position—The clip lay at the level of the intervertebral disc of T 11–12 in 75% of patients, and its position varied from the lower border of the 10th thoracic to the upper border of the 1st lumbar vertebra It was to the left of the midline in every patient, usually at the lateral vertebral border In the lateral view the clip appeared nearer the spine than the sternum in most patients, but in 2 it lay so far forward that it was nearer the sternum Its relationship to the diaphragm varied widely In 62% it was above, in 18% at, and in 20% below the level of the diaphragm In 3 patients it was well above the diaphragm (half or more of a vertebral body), and in 2 it was well below The clip could be located above the diaphragm in oblique views, but here there was great variation, depending mainly on the degree of obliquity of the patient (fig 1)

Supine and Trendelenburg positions—The most interesting feature in most subjects was the disproportionate cephalad movement of the clip relative to the diaphragm, the diaphragm ascended higher than the clip This was slightly more accentuated in the Trendelenburg position In some patients the relative positions of clip and diaphragm remained unchanged (figs 2 and 3), but an upward movement was present in every patient, usually of from half to one vertebral body The greatest move

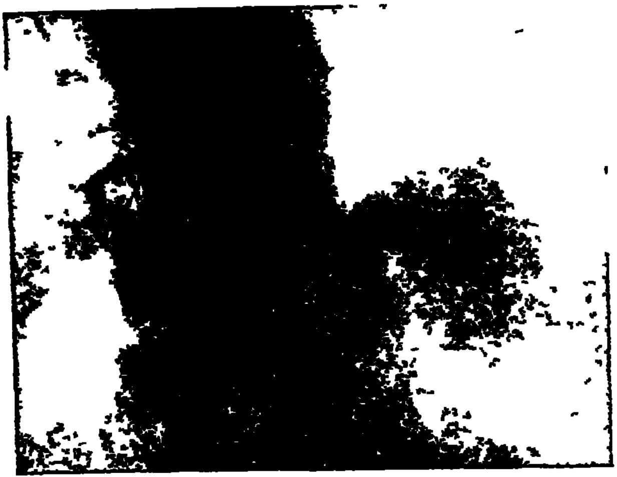

Fig 2—Supine the clip lies below the diaphragm

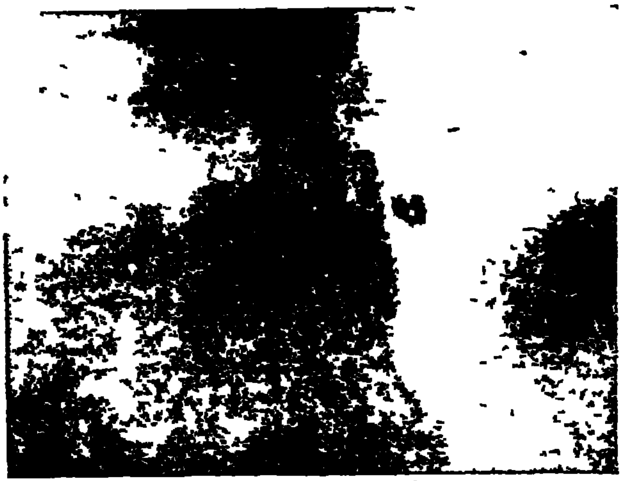

Fig 3—Supine. clip above the diaphragm

ment noticed was of two vertebral bodies (from erect, in expiration, to Trendelenburg, in expiration). A much bigger change in position took place on moving from the erect to the supine position than from the supine to the Trendelenburg. Not only did the clip move cephalad, but it tended to move to the left in most patients. In some, this shift to the left was absent. The clip was usually further from the vertebral column in the supine and Trendelenburg positions. The marker became a midline structure in the right lateral position and drew away laterally from the vertebral column in the left lateral position.

Position of Clip during Respiration

In most patients, the excursion of the clip was about one vertebral body during the respiratory cycle with the patient in the same position, but movement of two vertebral bodies was not uncommon. Though the clip moved up and down with the diaphragm, its excursion was less. During inspiration, the descent of the diaphragm was relatively greater and in most patients the clip was well above at the end of inspiration. During expiration the diaphragm ascended more than the clip did, so that in most patients it was at or below the diaphragm. The greatest excursion was observed in the supine position in a woman in whom the clip moved almost two and a half vertebral bodies.

During inspiration the clip moved medially as well as downwards. The extent of medial movement varied from patient to patient. In a few no medial movement at all was noticed. During expiration the clip moved upwards and slightly to the left in most patients. Together with the downward and medial movement on inspiration, the clip also moved posteriorly in most cases. This posterior movement was very slight and could sometimes only be seen when the lower œsophagus was displayed by means of the long balloon (fig 4). In a few patients it was absent, and in one the clip actually moved forwards during inspiration. Movement posteriorly during inspiration was much less than anterior movement during expiration.

Screening.—The radiographs were superior for accurate localisation but screening was by far the most valuable method of demonstrating the disproportionate movement of clip and diaphragm.

Discussion

In the first few patients examined, the discovery that the level of the clip was often above that of the diaphragm raised initial doubt (subsequently refuted) about the accuracy of placement of the clip on the hiatal margin. Therefore, in the succeeding operations, even greater care was taken to ensure precise anatomical fixation; moreover, correct positioning was confirmed in all the subjects by anteroposterior and lateral radiographs with the œsophagus demonstrated by barium or by the long opaque balloon.

Thus there can be little doubt that, in most people at least, the anterior margin of the hiatus is situated above the line that indicates the diaphragm radiographically. In only a minority is it at or below this level. This conclusion, which has been emphasised in a combined cineradiographic and manometric study of the gastro-œsophageal junction by Botha et al. (1957), agrees with the findings of Monges et al. (1955), who applied clips to the anterior hiatal margin and to both crura; post-operatively, X-ray examination showed that all three clips appeared above the diaphragm in that patient.

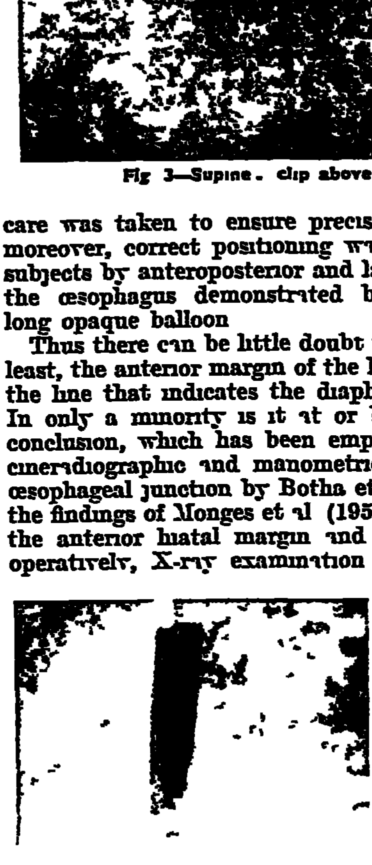

Fig 4—Left lateral, erect deep inspiration posterior movement was so slight that the balloon appears almost straight.

The relationship between the levels of the diaphragm and hiatus varies not only from person to person but also with posture and the phase of respiration. During inspiration the hiatus moves downwards, inwards and slightly backwards. Jouve-Fournier (1955) made the same observation with a radio-opaque balloon in the lower œsophagus.

The fact that the levels of the hiatus and the diaphragm do not necessarily correspond is significant for two important reasons. First, it means that various conclusions about the nature of the gastro-œsophageal closing mechanism have to be reconsidered—e.g., the manometric studies of Dornhorst et al. (1954) and the fluoroscopic observations of Poppel et al (1956), and secondly, it is important in the assessment of disease in this region, and it must be particularly remembered in the consideration of neoplasms, achalasia, diverticula, or hiatal herniæ

Poppel et al (1956) examined 500 subjects and saw "that the esophagus was indeed pinched off when the diaphragm descended in forced inspiration, however, this pinching-off did not occur at the level of the diaphragm but 0 5 to 3 cm above it It was in reality the constriction of the inferior esophageal sphincter that occurred synchronously with the descent of the diaphragm It was this action that was previously misinterpreted as a pinchcock action of the diaphragm" It is now clear that their inquiry did not reveal whether the constriction was due to hiatal action or to closure of the inferior œsophageal sphincter It is, furthermore, difficult to understand why the œsophageal sphincter should contract synchronously with the diaphragm

In considering the pinchcock action of the right crus, it is fundamental to appreciate that the crura act synchronously with the diaphragm, not independently of it Interesting diagrams in the past have convincingly demonstrated that the œsophago-gastric angle became more acute in inspiration The occluding effect of the mechanical valve at the cardia was thus accentuated, and gastro-œsophageal competence increased The present investigation, however, conclusively showed the opposite Disproportionate descent of the diaphragm and clip during inspiration opened the angle, which suggests that this factor is not so important in the closing mechanism as is commonly thought The wide variation in position and behaviour of the hiatus suggests that crural function may not be the same in every patient Too dogmatic views on crural action should therefore be regarded with suspicion

Palmer (1953) established the position of the "cardia" relative to the diaphragm after silver clips were attached to the mucosal junction at œsophagoscopy The same method was used to ascertain the degree of gastric herniation (Allison 1951, Palmer 1954) But if the hiatus is not at diaphragmatic level no conclusions can be drawn from minor upward or downward shifts of mucosal clips

Summary

The relative positions of the diaphragm and a radio-opaque marker on the œsophageal hiatus were studied in 20 patients

The position of the clip did not necessarily correspond to diaphragmatic level and there was considerable variation from patient to patient, in its position as well as in its movements The clinical, radiological, and experimental significance of these observations is outlined

I am indebted to Prof F A R Stammers, department of surgery, University of Birmingham, and the endowment research fund My thanks are due to Dr Roy Astley, radiologist to the Children's Hospital, for valuable suggestions, and to Mr T F Dee, photographer to the Queen Elizabeth Hospital, for the illustrations

A NOTE ON HEPARIN CLEARING IN VIVO

V FELT
M D Prague
RESEARCH FELLOW

D REICHL
D Chem Prague
RESEARCH FELLOW

INSTITUTE FOR CARDIOVASCULAR RESEARCH, PRAGUE, CZECHOSLOVAKIA

THE rôle of heparin in lipid metabolism has attracted the interest of many workers Since Hahn (1943) reported that intravenous heparin cleared the initial turbidity of plasma of dogs in alimentary lipæmia within a minute after injection

Kubie et al (1956a) have shown that intravenous heparin considerably depressed the polarographic protein double wave of human serum in alimentary lipæmia This depression has been attributed by Kubie et al (1956b), Marha (1955), and Reichl (1955) to the liberation of non-esterified fatty acids observed under such conditions by Grossman et al (1955)

Kubie et al (1956b) have also shown that, when precautions were taken to minimise in-vitro chemical changes in serum after the injection of heparin, the

* 1 blood taken in fasting state
2 blood taken 3 hr after ingestion of 300 ml of cream
3, blood taken 5 min after intravenous injection of 25 mg of heparin.
4 blood taken 15 min after intravenous injection of 25 mg of heparin

depression of the polarographic protein double wave was either small or absent It was therefore of interest to know whether the changes in optical properties of the serum were merely an in-vitro effect or also the result of physiological processes in the circulation

It is known that the catalytic effects of lipoproteinase, which is activated by heparin, can be prevented by the use of suitable inhibitors in vitro Therefore we examined the effect of intravenous heparin on the turbidity of serum obtained from blood to which an inhibitor of lipoproteinase had been added immediately after withdrawal of the blood to exclude any possible in-vitro effects

Material and Method

We examined sera from 8 healthy women and 5 healthy men In each case a sample of blood was taken while the person was fasting Each person next ate a fat meal consisting of 300 ml of rich cream Three hours later a sample of venous blood was taken, and with the same needle 12 5 mg of heparin in 5% solution was injected Exactly 5 minutes and 15 minutes after heparinisation further samples of blood were collected Immediately after collection 5 0 ml of blood was mixed with 0 5 ml of a solution of diethyl-*p* nitrophenylphosphate (' E600 '), a potent inhibitor of lipoproteinase The final concentration of inhibitor in the samples of blood was $1\ 10^{-4}$–$2\ 10^{-3}\ M$ As a control a further aliquot of the same sample of blood was mixed with saline solution in similar proportions The blood was allowed to clot at 37°C, and serum was separated by centrifugation at 3000 r p m The turbidity of the sera obtained was measured with the 'Unicam' photo-electric colorimeter with the red filter

Results

The addition of E600 to cleared serum in similar proportions had no effect on its turbidity under the same conditions

The results presented in the accompanying table show that, at sufficiently high final concentrations of E600 ($2\ 10^{-3}\ M$) there was practically no optical change within 5 minutes after heparinisation In subjects 3 and 4 there was even a slight increase in turbidity 15 minutes after heparinisation there was slight clearing, but in subjects 1 and 4 the turbidity was still unchanged Decreasing the concentration of E600 increased the extent of clearing The concentrations used in such instances ($1\ 10^{-4}\ M$ and $6\ 10^{-4}\ M$) were evidently too small to inhibit clearing entirely All the control samples without added inhibitor showed the well known dramatic decrease in turbidity (clearing) within 5–15 minutes after heparinisation The in-vitro clearing was relatively smaller in cases 1 and 4 who did not show any decrease in turbidity in the presence of E600 even 15 minutes after heparinisation

Preliminary experiments with plasma maintained at 0°C without added inhibitor did not show total inhibition of in vitro clearing

Discussion

The large differences in turbidity of sera with and without inhibitor emphasise the rôle of in-vitro processes caused by heparinisation Probably the sera obtained from blood treated with inhibitor have a turbidity approaching that existing in the circulation under physiological conditions This turbidity would be the net result of formation and disappearance of chylomicra from the circulation under given conditions This may explain the changes in turbidity observed at various intervals after heparinisation It may therefore be assumed that, 5 minutes after heparinisation (under the experimental conditions stated), the rate of formation of chylomicra exceeded the rate of their disappearance, only after 15 minutes after heparinisation did the rate of disappearance of chylomicra exceed their rate of formation (except in cases 1 and 4)

The enhancement of lipolysis by intravenous heparin may be the cause of an accelerated removal of fatty acids from the blood-vessels into the tissues The evidence presented here shows that an increased lipolytic activity causes in-vitro turbidity changes which have frequently been considered to represent in-vivo changes The use of a suitable inhibitor shows that, in alimentary lipæmia in man, 5 minutes after the intravenous injection of 12 5 mg of heparin there is practically no change in turbidity

We are indebted to Dr G Kubie for his interest and advice in the preparation of this manuscript

COLLAPSE and sudden death in patients suffering from pellagra is mentioned in textbook descriptions of the disease (Cecil and Loeb 1955) The possibility of a relationship between adrenocortical function and pellagra was first considered by Finotti and Tedeschi (1902) and has recently been reviewed by Mainzer (1950) Because syncope and collapse in pellagra are usually sudden, it must rarely be possible to carry out biochemical studies in patients who collapse We have found no reports of such studies which would clearly be valuable in deciding whether addisonian crisis and acute collapse in pellagra are accompanied by similar derangements of electrolyte metabolism For this reason we present details of a patient with pellagra in whom electrolyte and steroid estimations were made during an acute phase of her illness resembling addisonian crisis

Case-report

A widowed housewife aged 60 was admitted to hospital on June 10, 1955 Her appetite had always been poor, and for about a year she had lived on a monotonous diet consisting each day of 2 pints (1200 ml) of milk, some semolina, and six slices of a proprietary brown bread with small amounts of butter Occasionally she took very small portions of chicken During this time she lost 2 stone (12 5 kg) in weight In March, 1955, she had an attack of diarrhœa lasting a week, when she passed three watery yellow stools a day Subsequently her skin became dark on the exposed surfaces Early in May, 1955, she again started to have diarrhœa and occasionally vomited small amounts of bile stained fluid, these symptoms persisted till her admission. On May 28, 1955, she sat in the bright sunlight for six hours, and as a result the surfaces exposed became more severely pigmented

She was thin and mentally dull The whole skin showed brown pigmentation which was particularly evident on the exposed surfaces She had hyperkeratotic areas on the backs of her hands and feet and some brown pigmentation of her tongue Pigment was not concentrated in the skin creases The fæces were bright yellow and loose The blood-pressure was 100/30 mm Hg and her weight 6 stone 3 lb (40 kg)

She was seen by Dr I B Sneddon, who confirmed that the skin appearances were those of severe pellagra

Investigations —A radiograph of the chest was normal The hæmoglobin was 13 g per 100 ml The fæces contained no occult blood, and the fractional test meal showed a histamine-fast achlorhydria The urine and electrocardiogram were normal The Wassermann reaction was negative The serum-sodium was 137, serum potassium 4 6, serum chloride 97, and plasma alkali reserve 26 m eq per litre, and blood-urea 26 mg per 100 ml

Progress —On the morning of June 16, 1955, six days after admission, she felt very lethargic and weak after fasting overnight for a barium meal She appeared to be shocked and very ill, her blood-pressure had fallen to 60/0 The blood sugar was 115 mg per 100 ml, but the serum-sodium had fallen to 130 m eq per litre and the serum-potassium had risen to 7 4 m eq The serum chloride was 92 m eq, but the plasma alkali reserve was only 10 m eq The blood urea had increased to 83 mg per 100 ml

Treatment and Response —She was given nicotinamide 500 mg and two ampoules of vitamin-B complex ('Becosym') intramuscularly, and sodium lactate (1/6 molar solution) 3 litres intravenously in the next twenty four hours In addition she received cortisone acetate 25 mg orally six hourly for four doses By 4 30 p m on the same day she had improved and her blood pressure had risen to 110/80 The serum sodium was 126, serum potassium 6 6, serum chloride 98, and plasma alkali reserve 10 m eq per litre, and blood-urea 36 mg per 100 ml

Next day her blood pressure was 130/80, serum sodium 127, serum potassium 4 3, serum-chloride 89, and plasma alkali reserve 24 m eq per litre, and blood urea 25 mg per 100 ml

Treatment was continued with cortisone acetate (12 5 mg by mouth twice daily) for a further seven days and one ampoule of vitamin B complex once daily intramuscularly for twenty eight days During this time she improved further, she became more alert, her appetite returned, the diarrhœa ceased, and the stools became normal The pigmentation of the skin and tongue gradually faded with desquamation of the hyperkeratotic areas The blood-pressure was maintained at 100/70

Investigations after Completion of Treatment —Serum sodium 140, serum-potassium 4 0, serum chloride 103, plasma alkali-reserve 25 m eq per litre, and blood-urea 23 mg per 100 ml The liver function tests and a liver biopsy were normal A glucose tolerance test and a barium meal examination with follow through showed no abnormality A plain radiograph of the abdomen showed no adrenal calcification

Follow up.—She was discharged on Aug 4, 1955, and has been followed since this time She required no specific therapy and maintained herself on a normal diet In November, 1956, she had gained more than 2 stone (12 5 kg) and weighed 8 stone 6$^1/_2$ lb (53 6 kg) The pigmentation had almost completely disappeared The serum sodium was 144, serum potassium 4 9, serum chloride 103, and plasma alkali reserve 21 m eq per litre, and blood urea 21 mg per 100 ml A urinary chromatogram, kindly performed by Mr D C Cusworth in Prof C E Dent's laboratory at University College Hospital, London, was unlike that seen in the pellagra like syndrome with amino aciduria described by Baron et al (1956)

Urinary Steroid Excretion —On admission five days before the crisis, the twenty four hour excretion of 17 ketosteroids was 26 6 mg and of 17 ketogenic steroids 25 6 mg —values slightly higher than those normally obtained in this hospital's laboratory On July 8, 1955, twenty two days after the crisis and fourteen days after stopping cortisone, the 17-ketosteroid excretion was 5 0 mg and the 17 ketogenic steroid excretion 7 1 mg in twenty-four hours Next day the values were 3 5 mg and 7 4 mg respectively On July 19, 1955, she was given corticotrophin 25 mg intramuscularly six hourly for four doses The twenty four hour excretion of 17-ketosteroids was 11 0 mg and of 17 ketogenic steroids 26 0 mg This is a normal response On Nov 26, 1956, the 17-ketosteroid excretion was 3 1 mg and the 17 ketogenic steroid excretion 6 7 mg

Discussion

Pigmentation of the skin and mouth are presenting features in pellagra and in Addison's disease, and asthenia, loss of weight, and hypotension are common in both diseases Mental changes, diarrhœa, dermatitis, and light sensitivity help to differentiate pellagra from Addison's disease, but the fact that so many features are common to both diseases has given rise to speculation that hypocorticism may be a feature of pellagra

Necropsy studies of the adrenal glands in cases of pellagra have shown partial or even almost complete atrophy of the zona glomerulosa as the outstanding abnormality (Aschoff 1933, Froboese 1934, Herzenberg 1935, Eger 1937, Hellwig and Forman 1942) Variable loss of lipoid (Aschoff 1933, Froboese 1934, Herzenberg 1935, Eger 1937) and sclerosis of the capsule (Froboese 1934) have also been reported, but it is striking that the zona fasciculata and zona reticularis have remained virtually unaffected A few biochemical observations have been based on indirect tests of adrenocortical function Mainzer (1949) found increased insulin sensitivity in pellagra and concluded that this afforded evidence of hypocorticism Miowski and Tadzer (1954) using Thorn's test no 1, concluded that there was some disturbance of the diencephalic-adrenal axis There was only a small fall in circulating eosinophils after giving adrenaline and this was partially corrected by corticotrophin therapy

There is little doubt that our patient had pellagra with typical skin lesions and gastro intestinal disturbances which resolved with nicotinic acid and vitamin B complex There was a gain of more than 2 stone in weight in the year after her illness The symptoms did not recur, though she had no specific therapy after the acute phase of her illness The urinary chromatogram excluded the pellagra-like disease with amino aciduria as described by Baron et al

Before the acute episode, the urinary steroid excretion was slightly higher than normal and suggested an adrenocortical stress response During the crisis the normal blood-sugar level appeared to be an indication of adequate glucocorticoid activity During and after recovery the urinary steroid excretion and the corticotrophin stimulation test were also normal On the other hand, the sudden onset of hypotension, uræmia, and high serum-potassium at a time when no appreciable diarrhœa or vomiting took place suggested a failure of mineralocorticoid secretion Such findings are identical with those found in addisonian crisis

The results in our patient therefore suggest selective damage to the zona glomerulosa which is considered to be the main secretor organ of mineralocorticoids (Landing 1955) The fact that improvement was maintained for more than a year indicated that the lesion was reversible The reported necropsy findings of selective damage to the zona glomerulosa seem to provide a pathological basis for these biochemical changes

Our patient was treated with cortisone for acute adrenocortical insufficiency, but there is no evidence that recovery might not have resulted from treatment with nicotinamide and vitamin-B complex alone

Summary

The clinical and biochemical features of a crisis in a woman with pellagra suggest an acute failure of mineralocorticoid metabolism Reports of selective damage of the zona glomerulosa of the adrenal cortex in pellagra provide a possible pathological basis for this failure

We wish to thank Dr H P Brody under whose care this patient was admitted for his help and encouragement Our thanks are also due to Mr M J Lavell for the steroid estimations and to Dr D S Munro for correcting the manuscript.

GENERAL HOSPITAL, SOUTH SHIELDS

Granuloma of the umbilicus in young infants is not uncommon; but, whereas the part played by talc in the pathogenesis of granulomatous lesions within the abdomen and elsewhere has been clearly established (McCormick and Ramsey 1941, Roberts 1947), we have been unable to find any published report of a similar relationship in umbilical lesions.

In the past few months we have seen five cases in which such an association seemed to exist, as in the following one.

The infant was a healthy male delivered normally at term. The cord had separated at the seventh day, but the umbilicus did not heal, and a purulent discharge was present from the tenth day. "Something red in the navel" was seen at one month, and the discharge had continued unabated. Initially, sterile cord powder (conspers alum. et zinc oxid. pro infant. *B.P.C. 1954*) had been applied to the umbilicus, but subsequently a standard proprietary talcum baby powder was used.

On examination at six weeks the umbilicus contained a pink granulomatous mass of tissue, from which a purulent discharge exuded. Ten days later this was excised under general anæsthesia. Healing was satisfactory, and at three months the umbilicus was dry and the granuloma had not recurred.

Fig. 2—Talc crystals shown up by polarised light in umbilical granulations.

Histology

On microscopy these specimens present a gradation of features on a common background of heavy non-specific infection, which is related to the extent to which the talc crystals become incorporated into the granulation tissue. In some areas these may be wholly confined to the superficial inflammatory exudate; but, where the doubly refractile particles are situated more deeply, various degrees of giant-cell formation are found. In the actively inflamed areas this is generally slight or absent; but, where connective tissue has become organised, the talc crystals are seen in distinct aggregates, with conspicuous multinucleated giant cells. These, however, are of typical foreign-body pattern, and in no instance have we found any indication of endotheloid cell elements of follicular structure.

Discussion

In a review of disorders of the infant umbilicus Isbister (1953) considers that the umbilical granuloma, as distinct from the umbilical polyp of intestinal tissue, is usually secondary to infection. The finding of doubly refractile crystals in these granulomata must pose the question as to how often such lesions are sustained by the free use of talcum powder with which most infants are dusted from birth, particularly in view of the fact that, though such lesions are not uncommon, surgical biopsy is hardly ever resorted to.

In these cases the course of events differs from that associated with talc granuloma of the peritoneum and fallopian tubes because, in the early stages the formation of granulation tissue has not been initiated by the talc crystals, the umbilical stump healing normally by this process. There is little evidence at first of any active tissue response to their presence, as shown by the lack of foreign-body reaction, from which it seems that the crystals delay the healing largely by creating conditions favourable to the persistence of infection, and only at a later stage, when acute inflammation has subsided, does giant-cell reaction clearly develop. Possibly, after a further lapse of time, a pseudotuberculous picture might develop corresponding to those described after the traumatic introduction of silicious particles into the subcutaneous tissues (Shattock 1916, Faulds 1935) and in surgical scars (Feinberg 1937); but there are no grounds for suggesting that any long-term detrimental effects may develop in such cases.

Fig. 1—Umbilical granulations.

It seems, however, reasonable to suggest that such potentially irritant powders should not be used, at least before the umbilicus is soundly healed One might indeed go so far as to advocate that the routine use of talcum powder should be abandoned because in no circumstances can it be a substitute for proper cleansing of the skin, followed by thorough drying, but in this matter we are concerned with a ritual which is too firmly rooted in tradition to be influenced by considerations such as these

RENAL COLIC AND PERSISTENT HYPERCALCURIA FOLLOWING SELF-ADMINISTRATION OF VITAMIN D

P Freedman
M D Lond, M R C P
RESEARCH ASSISTANT,
MEDICAL UNIT, UNIVERSITY COLLEGE HOSPITAL, LONDON

Hypercalcuria has become of increasing interest to both physician and surgeon the physician sees it as an expression of endocrine disorders, biochemical disturbances, and renal pathology,[1] whereas the surgeon is more directly concerned with the increased tendency to renal calcification and lithiasis

Hypercalcuria and renal colic in the case here reported appear to have been caused by a prolonged course of vitamin D which was self-prescribed The increased urinary excretion of calcium is still present fifteen months after the vitamin has been discontinued

Case-report

A male cook, aged 55, was first seen in the casualty department at 5 A M with severe pain which had come on suddenly in his left loin and awakened him two hours previously The pain was severe and colicky and radiated into his left groin He could not lie still while the pain was present, but there was gradual relief after an injection of pethidine There was no macroscopic hæmaturia, no disturbance of micturition, and no history of previous similar episodes No other relevant past history was given at this time, and there was no significant family history

On admission the patient appeared to be otherwise fit, with no abnormal physical findings in the cardiovascular system or lung fields Blood-pressure 110/70 mm Hg His kidneys were impalpable, and tenderness in the left renal angle rapidly disappeared There were no other abnormal physical findings The first specimen of urine passed contained very numerous red cells, occasional pus cells, and no protein The urine gave a strongly positive Sulkowitch reaction for calcium and tests for cystine were negative Further inquiry of the patient elicited a history of taking "vitamin tablets" as a general tonic for the past three years These proved to be a proprietary vitamin preparation ('Ostelin,' Glaxo) containing 50,000 units (1 25 mg) of vitamin D (as calciferol) in each tablet, which also contained 105 mg of calcium and 44 mg of phosphorus

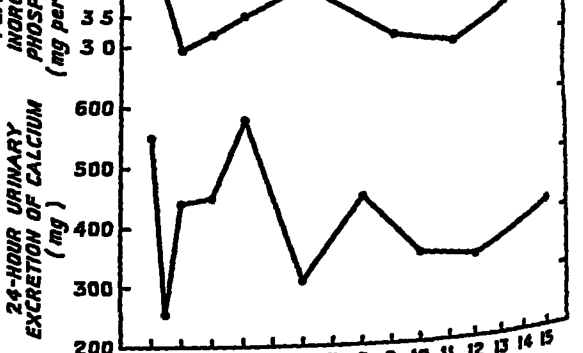
Investigations—On the day after admission the urine contained 3 red cells per $^1/_6$ field, no pus cells, no casts, and no protein, and was sterile on culture The blood urea level was 30 mg per 100 ml, and the urea clearance was 93 5% maximum and 88 5% standard The hæmoglobin was 108%, erythrocyte sedimentation rate 10 mm (modified Westergren read in 100 mm tube) in the first hour, and white cell count 9800 per c mm (differential count normal) The initial values obtained for the serum calcium level were 10 0 and 9 8 mg per 100 ml and plasma inorganic phosphorus level 4 6 and 4 6 mg per 100 ml Straight radiography of the abdomen and an intravenous pyelogram revealed no abnormality in the urinary tract, and there was good concentration of diodone Radiography of the chest showed old calcified lesions at both apices, but specimens of sputum contained no acid fast bacilli Radiography of the skeleton showed an enchondroma in the fourth proximal phalanx of the right hand but there was no evidence of generalised disease of bone The twenty four hour urinary excretion of calcium was 550 mg In view of this high value further investigations were undertaken The plasma alkaline phosphatase level was 11 0 King Armstrong units per 100 ml, the plasma electrolyte, carbon dioxide capacity, and serum protein levels were normal, and the serum flocculation tests were negative

Progress—It was considered clinically that the attack of renal colic was probably associated with his hypercalcuria and with the passage of a small stone, although this was not actually seen The vitamin D preparation was discontinued on admission, and a week later the urinary excretion of calcium was 255 mg in twenty four hours The patient was discharged, nine days after admission, on a low calcium and vitamin-D poor diet, achieved by a severe restriction of his intake of milk and dairy produce, and has been seen regularly for follow up during the past fifteen months Clinically he has remained well and has had no recurrence of renal colic or any symptoms connected with micturition Repeated estimations of the twenty-four hour urinary calcium while on a low intake have shown a persistently excessive excretion (see figure) over the accepted upper normal limit of 220 mg for this laboratory The diagnosis of renal tubular acidosis was considered unlikely in view of the normal plasma bicarbonate levels, and the failure, on two occasions, of sodium bicarbonate, in a dosage of 10 g daily for seven days, to reduce the excessive output of calcium was further evidence against this condition as a cause of the hypercalcuria The serum calcium level fell during the early months of follow up (see figure) and still remains low (8 9 mg per 100 ml) The plasma-inorganic-phosphorus level has varied during the period, and, although low values have been recorded (see figure), the most recent value was 4 0 mg per 100 ml Repeat estimations have given normal values for the plasma protein levels, the urine has remained free from protein and is normal on microscopy, and radiologically there is no evidence of calcification in the kidney or of generalised disease of bone The blood urea, plasma potassium, and plasma bicarbonate levels have remained normal, and the most recent alkaline phosphatase level is 6 9 King-Armstrong units per 100 ml

Discussion

Increased urinary excretion of calcium has long been recognised as an important association of calcification within the kidney and of an increased likelihood of calcium lithiasis

Flocks (1939, 1940) found that the excretion of calcium was raised in about two thirds of 35 unselected cases of calcium urolithiasis Furthermore, all patients with recurrent or



Changes in serum-calcium and plasma inorganic-phosphorus levels and twenty-four hour urinary excretion of calcium during follow-up period of fifteen months after end of long course of vitamin D rapidly-growing stones had a high urinary calcium Many of the patients with calcium stones had a high urinary calcium without any bone disease or evidence of hyperparathyroidism, change in blood-calcium level or blood-phosphorus level, or other demonstrable abnormality of calcium metabolism These patients responded to an acid ash diet and to vitamin D with an exaggerated increase in the urinary excretion of calcium

Albright and Reifenstein (1948), considering the metabolic disorders leading to hypercalcuria, divided them into those associated with hyperparathyroidism, osteoporosis during the stage of progression, renal acidosis, and those in whom no other abnormality was found This latter group, which they consider is probably the more common, they called idiopathic hypercalcuria, and they drew attention to a "tendency" to a low serum calcium level in this condition

Albright et al (1953) discussed further the problem of idiopathic hypercalcuria 22 patients had shown hyper calcuria with normal serum calcium and low plasma-phosphorus levels and, in most cases, evidence of past or present pyelonephritis There was also a high incidence of stone These workers suggested that infection damaged the renal tubules, thus causing hypercalcuria, a low serum-calcium level, and, possibly, by an ensuing overaction of the parathyroid glands, a low plasma inorganic phosphorus level

Pyrah and Raper (1955) examined radiologically 216 apparently healthy kidneys removed at necropsy and found small calcified foci in 10% of them. Microscopy of 206 healthy kidneys showed tiny calcified foci in 21%, and this figure might well have been higher if serial sections had been used These calcified foci were mainly found around the upper collecting tubules, but a few lay within the lumen of the tubules The origin of these foci, whether in minor pathological lesions which had healed or in temporary biochemical disturbances, was not determined

In children renal failure is sometimes associated with hypercalcæmia produced by hypervitaminosis D In the adult, renal damage following vitamin D administration is sometimes seen after long courses of calciferol given in the treatment of lupus The serum-calcium level rises, and renal-function tests show considerable impairment of function, often after many years

Dent (1954, 1956) has surveyed the influence of vitamin D on the excretion of calcium and phosphorus Among its many actions the vitamin promotes the intestinal absorption of calcium with a consequent decrease in fæcal calcium, and increases the urinary excretion of calcium even when given in doses insufficient to produce hypercalcæmia Dent has also drawn attention to the wide range of individual sensitivity to vitamin D

Care was taken in the present case to exclude the above mentioned conditions known to be associated with excessive urinary excretion of calcium The fall in the serum calcium level is of recent onset because the values were normal when the patient was first seen and declined subsequently Possibly the long-continued hyper calcuria associated with the administration of vitamin D caused persistent damage to the renal tubules and consequent continued excessive loss of calcium in the urine The gradual fall of the blood calcium level suggests that osteomalacia may appear in the future if the excessive excretion of calcium continues, and in this situation further stones and renal calcification are additional potential hazards

Vitamin D is at present added to many food preparations, in particular those used for infant feeding Since there is wide variation in individual sensitivity to the vitamin, and since severe toxic effects and persistent renal damage may follow hypercalcæmia and hypercalcuria as a result of excessive vitamin-D action, the advisability of this practice is being reviewed (British Pædiatric Association 1955) The danger is the greater for infants whose parents have been strongly encouraged to give further supplements of vitamin D in the form of cod liver oil or other concentrates The possible role of abnormal sensitivity to vitamin D in the pathogenesis of idiopathic hypercalcæmia in infants has been reviewed previously (Lowe et al 1954, Creery and Neill 1954, Bonham Carter et al 1955)

The present case has shown that not only are the known hazards present during the administration of the vitamin, but also that one complication—i e, hypercalcuria—may persist for a long time after other signs of overdosage have disappeared. It therefore seems likely that the exhibition of vitamin D, not necessarily in high dosage if combined with abnormal sensitivity, may be one of the possible causes of so-called "idiopathic hypercalcuria," perhaps presenting with its own train of complications long after the period of administration The history of such a course, if recalled by the patient, will almost certainly have been dismissed by him as irrelevant

The unrestricted sale of potent vitamin-D preparations may well need review in the light of such considerations

Summary

A patient is reported who, after prolonged self-administration of vitamin D, was admitted to hospital with renal colic presumed to be due to the passage of a small renal stone

Hypercalcuria was present without hypercalcæmia and persisted for at least fifteen months after the vitamin had been withheld This is assumed to have been induced by the vitamin D and to have been the cause of the renal symptoms

I wish to thank Dr A G Spencer, under whose care the patient was admitted, for permission to publish, Prof C E Dent for his constant help and advice, and Dr F V Flynn and the technical staff of the biochemical laboratory of University College Hospital for the estimations

Preliminary Communication

CYTOPATHIC EFFECT ON PRIMATE AND RODENT TISSUE-CULTURES OF AGENT ISOLATED FROM MEASLES PATIENT

In 1954 Enders and Peebles[1] reported the isolation and passage, in tissue cultures of human or monkey kidney, of measles virus from the blood and throat-washings of patients Multiplication of the virus in the cultures was accompanied by characteristic changes in the cells—namely, formation of vacuolated syncytial giant cells in which the nuclear chromatin assumed a marginal position and was replaced centrally by an eosinophilic inclusion body surrounded by a clear halo In measles patients significant increases in neutralising antibody against the cytopathogenic agent developed Complement fixing antigen developed in the nutrient fluid of infected cultures, it reacted with convalescent-phase sera, but not with acute-phase sera, from measles patients

The present investigation was undertaken with two objects (1) to isolate from measles patients in London an agent producing cytopathic effects similar to those described by Enders and Peebles[1], and (2) in the event of success, to grow this agent in cultures of tissues more readily available than human and monkey kidney

---

[1] Enders J F Peebles T C *Proc Soc exp Biol N Y* 1954 86 277

ISOLATION OF AGENT FROM CHILD WITH MEASLES

Nose and throat swabs were taken from a measles patient within 24 hours of the appearance of the rash The swabs were inoculated into the nutrient fluid (medium 199) of a monkey kidney tissue culture After 10 days' incubation at 36°C vacuolated syncytia were observed With continued incubation the cytopathic lesions increased in size and number The culture was stained on the 20th day after inoculation and numerous eosinophilic intranuclear inclusions were seen The nucleoli were preserved

GROWTH OF AGENT IN CULTURES OF PRIMATE AND RODENT TISSUES

Eleven passages of the agent were made in monkey-kidney tissue cultures, and cytopathic changes similar to those in the primary culture were seen at each passage level

Nutrient fluids from monkey kidney cultures showing typical cytopathic changes were used for inoculating tissue cultures of human infant kidney (excised), human amnion, human chorion, epithelial-like cells derived from human kidney by Chang,[2] HeLa cells, chick embryo lung, and the kidneys of a 5 week-old hamster, an 8 week old mouse, an embryo guineapig, a 5 day old guineapig, and an adult guineapig In all these tissue cultures, except of chick embryo lung, cytopathic changes developed which, during incubation and on staining at the 10th–20th day after inoculation, were essentially similar to those seen in the infected monkey kidney cultures Uninoculated tissue cultures of each type were incubated and observed, but no similar cytopathic changes were seen in them

Positive results were obtained in complement fixation tests using human convalescent measles sera and, as antigens, nutrient fluids from cultures showing cytopathic changes The results with nutrient fluids from uninoculated cultures were negative

COMMENT

There can be little doubt that the cytopathic changes in the inoculated tissue cultures were due to measles virus This view is supported by the fact that the primary culture had been inoculated with swabs from a patient in the exanthematous stage of measles, that antigens of the infected tissue cultures fixed complement in the presence of convalescent measles sera, and that the cytopathic changes were similar to those which Enders and Peebles[1] found in tissue cultures of human kidney or monkey kidney inoculated with measles virus Recently, other workers have reported the growth of measles virus in cultured cells of human origin (Jordan,[3] Dekking and McCarthy,[4] Black et al[5]) The results of the present investigation would seem to indicate that measles virus can be grown not only in cultures of primate tissues but also in those of rodent tissue Further work will be required to confirm and extend the investigation It will be of interest to see whether virus from measles patients can be isolated in rodent tissue cultures, and whether the virus can be serially propagated in such cultures Progress with this method would permit study of measles virus in the tissues of a small and conveniently obtainable animal, and a gain in knowledge regarding virus specificity

I thank Dr C H Andrewes for his encouragement and valuable advice, Dr T B Williamson and Dr G D W McKendrick for facilities for the work, Dr A Isaacs Dr H G Pereira, Miss D M Chapronière, and Mr L G C Maslen for their interest and help, Dr A P Goffe for monkey kidney cells, and Mrs R Villanueva for technical assistance

New Inventions

A DROP-TILT BED FOR THE LABOUR WARD

ABOUT two-thirds of maternal deaths associated with anæsthesia are caused by inhalation of stomach contents It is usually emphasised that such deaths are avoidable, but there is lack of agreement on the method of prevention

Gibberd[1] proposes a postural method and describes a labour-ward bed which can be tilted into a head-down position at a moment's notice by a simple movement of the anæsthetist's foot He says "The proper management of regurgitation of stomach contents . . . is to recognise it immediately, and immediately to lower the [patient's] head so that postural treatment has been adopted *before* [italics mine] the vomit can be inhaled" The essence of this method is its simplicity, but it cannot be used effectively unless the right type of bed is available Many labour-ward beds have no tilting device at all, some can be tilted by mechanisms which require manual operation and involve dangerous delay Delayed action is not enough Instantaneous action, which will save lives and prevent near fatalities, depends on a *split second* tilting device operated by the anæsthetist Gibberd rightly insists on the device being foot-operated so that the anæsthetist's hands are free for the performance of other urgent duties Head-harnesses for keeping the

[1] Gibberd G F *Lancet*, 1955, i 901

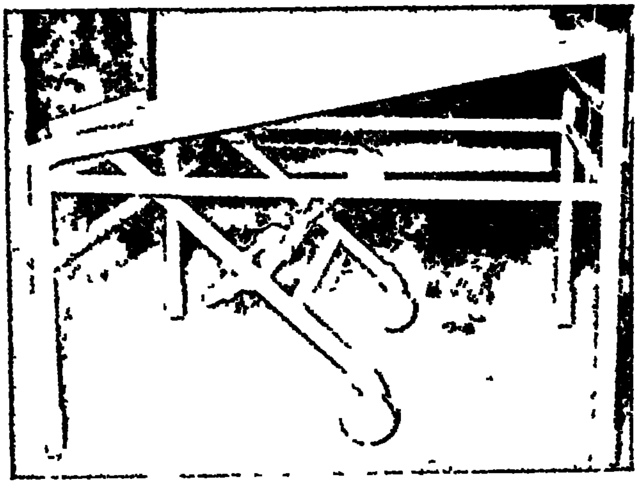

Fig 1

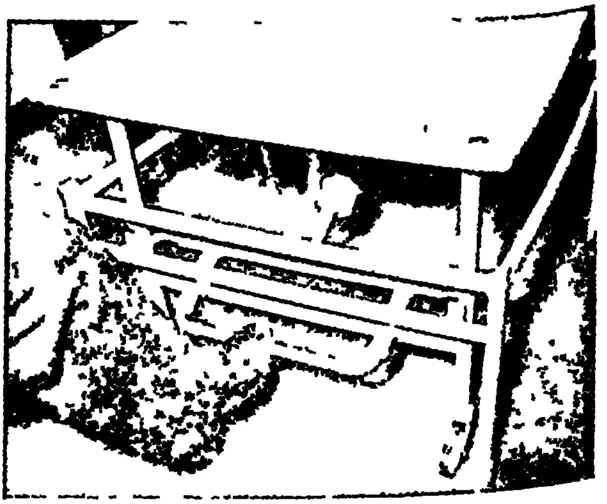

Fig 2

anæsthetic mask in position have no place in the labour-ward

I hope that the bed described here will focus attention on the postural method again and make possible a more general application of the principle of foot-operated drop-tilting

The bed is made in two sections a rigid section which supports the patient's legs, and a tilting section The rigid section (not illustrated) is on castors and can be easily disconnected from the tilting section and wheeled away. A rubber mattress covers each section

Fig 1 shows the tilting section in its head-down position. This tilt can also be obtained while the rigid section is in place, the patient's legs remaining on the rigid section while the rest of her body tilts It is therefore safe to induce anæsthesia before removing the rigid section and placing the patient in the lithotomy position The lower ends of the lithotomy poles can be seen in their holders

Fig 2 shows the locking device being released The wheel-bearing legs are prevented from running backwards by the lower of the two cross-bars which connect the short rear legs They cannot run forwards until the locking device is released This device is kept locked by the cylindrical lead weight It is released by the anæsthetist placing his foot on the kick-bar with sufficient force to counteract the effect of the lead weight The two U-shaped side-arms of the locking device are now clear of the cross-bar, against which they are normally held by the weight One simple movement of the foot unlocks the legs and starts them on their forward journey The patient, deprived of the support of these legs, drops into a head-down position Shock is absorbed by two small rubber buffers

When the tilted platform is lifted back to its normal horizontal position, the chain automatically pulls the legs back to their vertical locked position

The two holes which can be seen near the rear edge of the tilting platform are sockets for a removable head-rail

The major problem in design was to achieve stability Because the top surface tilts by pivoting round a rod which connects the upper ends of the front legs, any forward drag on the top surface will cause these legs to tilt forward Such drag occurs when traction is applied to the obstetric forceps and when the patient moves, or is moved, forwards on the bed Any forward tilt of the front legs is transmitted as an upward movement to the lower side-bars, which would lever the short rear legs off the floor This is prevented by a small metal plate on each wheel-bearing leg projecting over similar plates on the lower of the two cross-bars which connect the short rear legs Upward movement of these legs being stopped in this way, forward tilting of the front legs cannot take place The result is complete stability

This bed is now in use at the War Memorial Hospital in Nakuru, Kenya It was made locally The framework is made of British Standard Pipe, and the U-shaped pieces of the locking device are standard one-inch cross-overs

I wish to thank Mr Gustav Kramer for presenting the bed to the hospital, Mr Robert Heller and Mr Hans Gordon for the constructional work, and Mr A. G Kavlor for the photographs

How to Live With Your Rheumatism

OSWALD SAVAGE, O.B E, M.R.C.P Pp 142 8s 6d

Family Doctor books London British Medical Association 1956

HERE are four essays in the widely practised but difficult—if not dangerous—art of expounding medicine to the layman ignorant of anatomy and physiology

One of the four is addressed solely to those with a proved duodenal ulcer, and one to sufferers from "rheumatism"—a clinical concept, if scarcely an entity But we all have a blood-pressure and nerves, we can all start looking at them and wondering about them, if encouraged, and some of us will almost certainly be healthier people and better patients if we know that we know nothing about them and are content to be ignorant than if we have the wealth of information here provided—more especially on blood-pressure

The crucial experiment of giving these books free to every appropriate reader in, say, Gloucester, while withholding them from all the citizens of Worcester, and shrewdly questioning a good big sample of patients and doctors in each city five years later, cannot be performed but it is probably fair to say that while a doctor could hand out *Duodenal Ulcer* or *Rheumatism* without hesitation he had best size up his man or woman before giving them *Nerves* or *Blood Pressure*

What can be said for certain is that all four books are well informed, up to date, and written with the single intention of helping the reader and his doctor

The Scientific Investigation of Crime

L C NICKOLLS, M SC A R C.S, F.R.I C, D.I C, director, Metropolitan Police Laboratory, New Scotland Yard London London Butterworth. 1956 Pp 398 50s

THE quality and usefulness of technical books on the scientific investigation of crime have improved remarkably in the past ten years Paul Kirk Svensson, and others have set a high standard, and any new book in this field must compete at the same level or fail Apart from the Hans Gross, which was written for routine police use, no English authority has attempted this task until now

Mr Nickolls, whose position as head of the forensic science laboratories at Scotland Yard provides him with abundant material, has made excellent use of it in this quite small and very practical handbook In the physical sciences the material, though restricted, covers the ground very well Not everyone will regret that British experience in firearms is too meagre for any forensic textbook from this country to compete with those from other parts of the world where gunplay is more familiar The section on wood, hairs, and fibres is particularly comprehensive for so small a book Those who would expect Mr Nickolls's specialty of forensic toxicology to receive lengthy treatment are put right in the introduction, where it is made quite clear that nothing more than a short review of method will be found in the toxicological section Those who want to go further into any subject have a full bibliography to help them For a start, however, this book gives them an authoritative and well-illustrated guide

The Cytology of Effusions in the Pleural, Pericardial and Peritoneal Cavities

A I. SPRIGGS, D M, M R C P London Heinemann Medical Books 1957 Pp 71 £2 2s

THIS atlas is intended for use "with the standard hæmatological atlases in order to help in the identification of the cells of pleural, pericardial and peritoneal fluid" It is surprising how old this subject is, and Dr Spriggs considers that it has been neglected because poor techniques have given poor results With proper technique much more can be made out of the cytology and, in particular, the study of the cells in these effusions may help to disclose malignant conditions

Dr Spriggs gives a clear account of his not too complicated technique, which demands nothing not already in the clinical laboratory and uses the standard May Grunwald Giemsa blood stain The results are illustrated in 5 colour plates made from paintings by Gereth M. Spriggs These plates are very good clearly printed, with well reproduced detail, and the cells are represented at a proper size so that they give a true idea of what will be seen in the microscope There are also 40 photomicrographs in monochrome, these are, on the whole, very good too though some suffer more than others from the inevitable lack of clarity of high power magnifications They certainly convey the variety of appearances encountered in the different conditions It is interesting to see that positive diagnostic results were obtained in 71% of pleural or peritoneal effusions due to malignant disease

The text is purely descriptive, and two chapters are devoted to this important matter of malignant effusions Dr Spriggs lists the criteria of malignancy but adds the warning that "none is pathognomonic and in practice conviction comes with experience and not with enumeration of criteria" We agree heartily

This, then, is a useful atlas which should encourage clinical pathologists to take more care with cytological preparations from pathological exudates, and so extract more information from them

The Child and the Family

First Relationships D W WINNICOTT, F R C P London Tavistock Publications Ltd 1957 Pp 147 12*s* 6*d*

IN this book are collected many of Dr Winnicott's radio talks about babies and young children and their parents

At his best Dr Winnicott has a poetic gift of expression, and he is at his best when talking to what he believes to be an unsophisticated audience When he speaks to the "ordinary devoted mother" or "normal parents" of the immensely important part their normal loving impulses play in the growth of the individual and society, he is to a certain extent idealising his audience The implication is that any departure from this idealised normal is the result of adverse external influences, the normal mother knows how to deal with her newborn baby unless her self confidence is shaken by those caring for her This has been at least partly true—the expert in physical care often does not appreciate how closely interwoven are the physical and psychological in babies and young children But many would not agree with Dr Winnicott's criterion of "normality," believing that it is "normal" for parents to feel irritation or anger with their offspring at times, and that the all loving, all giving parents would cause their children to feel great guilt Also it cannot be denied that many of the doubts which beset parents come from within, even if they are sometimes reinforced by the experts There must be few parents (however "normal") who have not felt that they were at least temporarily losing their way with one or another of their children

Few who try to help parents and children would not be glad of some of Dr Winnicott's perceptiveness and gift of communication This book may be most helpful to those to whom it is not directly addressed—experts on maternal and child care, general practitioners, nurses, obstetricians, and pædiatricians

Statistics of Therapeutic Trials

G HERDAN, M SC, PH D, LL D, lecturer in medical statistics, University of Bristol New York Elsevier Publishing Co London Cleaver-Hume Press 1955 Pp 367 50*s*

THIS is a disappointing book, although the author has an erudite and novel approach to teaching the application of statistical method to clinical trials

Instead of the more conventional systematic progress through the development of statistical concepts and techniques with illustrative examples on the way, he has started with a series of practical problems for which he prescribes the appropriate statistical method of analysis This is an attractive approach, but anyone who had read no other text on medical statistics might find himself at a loss when faced with a situation not covered by the series of prescriptions By cutting out the mathematics and giving the formulæ dogmatically a deceptive air of simplicity is achieved The standard deviation, for example, is dealt with in eight lines, and this may lead to a rather mechanical and unrealistic approach in practice If the rational basis of tests of significance is too briefly emphasised, the discussion of the design of clinical trials is rather long and at times obscure Those with practical experience in the conduct of clinical trials may be surprised by the author's failure to comment on the limitations of strict alternation or the importance of selection in the interpretation of the published comparison between survival times after various forms of cancer therapy

In short, although experienced workers will find some *stimulating ideas in this work, it cannot be recommended* as an introduction to the subject

The Adrenal Cortex

I CHESTER JONES, B SC, PH D, lecturer in zoology, University of Liverpool London Cambridge University Press 1957 Pp 316 37*s* 6*d*

THIS monograph, which treats the subject from the angle of comparative physiology, is particularly valuable since reports on different species are apt to appear in widely different types of specialist journals, and it is only too easy to miss relevant work

The clinician will be interested chiefly in the first and longest section of the book, which deals with the Eutheria, and in the last sections, where the embryology of the organs is considered and the author attempts to correlate structure and function In dealing with the Eutheria, after considering the gross and microscopic anatomy of the glands and the chemistry and biosynthesis of their hormones, the author discusses the control of adrenocortical secretion and devotes a long subsection to function Particularly interesting at present is the section on water and electrolyte metabolism and the possible coordination between the adrenals and the posterior lobe of the pituitary There is also a useful summary of what are called natural abnormalities of function—i e, diseases arising from hyper or hypo function of the adrenal cortex The diagrams and photographs are clear and the *price is reasonable*

This book will be much appreciated by anyone working in the field of endocrinology

---

A Textbook of Psychiatry (8th ed London Oxford University Press 1956 Pp 745 35*s*)—The changes in "Henderson and Gillespie" do not appreciably alter its merits and defects Edited by Sir David Henderson with the help of Dr I R C Batchelor, it remains a well organised coherent statement of middle of the road psychiatry Contentious matters are treated with easy tolerance rather than intellectual rigour, and the citation of authorities is somewhat arbitrary With the advent of Dr Batchelor, the chapter on epilepsy has been recast and some of the discussion of ætiology amplified, the distinction between schizophrenia and paranoid states, asserted in recent editions, is now confidently treated as established, though one of the three reasons given—that patients with paranoid states "rarely exhibit the gross intellectual and emotional deterioration which is so characteristic of schizophrenia"—is questionable as fact and perhaps contains a *petitio principii*

Biographical Memoirs of Fellows of the Royal Society (Vol 2 London The Royal Society 1956 Pp 345 30*s*)—Nearly half of these twenty one masterly biographies deal with medical men or scientists who have worked in close touch with medicine Each includes an assessment of the contribution made to science, a detailed bibliography of published work sometimes of astonishing length, and a signed photograph of unusual excellence Of how many scientists could it be said that "the secret of his greatness is probably that he could recognise a problem that could be dealt with by experimental methods, that he could then reduce the experimental technique to something very simple and that in carrying out the experiment he could distinguish the essential points from the confusing details" Physiology is represented by Gleb Anrep, biochemistry by Harold King and Otto Rosenheim, experimental pathology by Charles Martin Bacteriology has lost O T Avery, Alexander Fleming, and Richard Pfeiffer Patrick Buxton made entomology his life's work, Sheldon Dudley epidemiology, and J A Sinton tropical medicine The biographies cover many subjects including advanced mathematics, philately, and nonsense verse with an unexpectedly amusing illustration It cannot be often that a publication of the Royal Society includes representatives of the two senior Services Sir Sheldon Dudley was medical director general of the Royal Navy during the 1939–45 war, and Brigadier Sinton did valuable work on malaria for the Army This series of biographies is of world wide interest and importance

A Therapeutic Index (2nd ed London Baillière Tindall, & Cox 1957 Pp 156 12*s* 6*d*)—For the new edition of this practical handbook by Dr C M Miller and Dr B K Ellenbogen some sections have been extensively revised and a few new ones added; and the antibiotic dosage tables have been modified

THE LANCET

LONDON SATURDAY MARCH 30, 1957

"Withdrawal"

THE choice may not be easy, but it is necessary. Doctors cannot have both the prestige of a profession, whose strength lies in the merits of its case, and the power of a trade union which is organised to apply pressure. In the public mind Dr Jekyll's status as the beloved physician will not survive his repeated transformation into Mr Hyde, the medical workman, who is ready to use political force in his own interest.

Granted its premises, the British Medical Association's plan[1] for constraining the Government is a good one: it does not come into action till October, and, even after it begins, its development by stages makes it at first no more than a warning of what is to come. But, though every chance is to be given to the other side to come to terms, the possibility remains that their resistance will harden and that a struggle will take place. In this, we are told, the aim would be to embarrass the Government without inconveniencing the public, yet it is hard to see how the Government would be embarrassed except in so far as the public were inconvenienced. True, no patient would be deprived of medical help, but he would normally be expected to pay for it and people might be as much upset by this as they would be if, in a railway strike, they were told that their season tickets had been cancelled but they could get to work by paying the railwaymen a special fare. The action recommended by the General Medical Services Committee is not a strike in the sense that services are to be withheld: doctors work for their patients, not for the Government, and they are going to continue this work, though under fresh arrangements of their own. But it would none the less be regarded by the public as a strike, because it is an attempt to secure better pay by threatening to make the paymaster's organisation unworkable. It is well to recognise, too, that sooner or later hostile critics would point to the advantage enjoyed by doctors in such a dispute—namely that, whereas the worker in industry risks his wages when he threatens to walk out, the doctor knows that many of his patients will not dare refuse him fees.

In giving these indications of the awkwardness of combining professional and trade-union techniques, we shall be told that the latter have often been used in the past *pro re nata*, without affecting the status of the profession, and that now (as sometimes before) they are the only means of getting the Government to pay attention to injustice. But the B.M.A.'s many unquestionable successes have not in fact been gained without cost—though, oddly enough, it is often those who believe most strongly in forceful methods that are readiest to note and deplore a less respectful attitude towards doctors nowadays, just as they are often the people who are particularly keen to keep medicine "out of politics". As for the argument that attention is paid only to negotiators who get tough, we believe, on the contrary, that nothing would be so likely to appeal to the sense of fairness of British Governments as the knowledge that they were dealing with a profession which in no circumstances would use its political weapons. For the present this moral asset has been thrown away, and doctors are urged to embark on a trial of political strength, on a purely monetary matter, in which it is far from certain that public opinion would be on their side.

The handling of medical remuneration by successive Governments has been lamentable: as we said earlier this year,[2] they have behaved not like partners in the enterprise of National Health but like intransigent and short-sighted employers. But the profession is itself to blame for losing opportunities to urge a review which might by now have provided a firmer and more durable basis than the Spens reports.[3] Moreover, the only Government that concerns us at the moment is Mr MACMILLAN's, and in his short time as Premier he can at least be said to have paid attention and taken action, even if we do not think it the right one. To the man-in-the street it may well seem that "something on account," and an inquiry intended to produce a permanent settlement, is a sensible way of dealing with an obviously complex problem, and in the present critical industrial situation his sympathies will probably be with the Government rather than with any group which seems to be asking favoured treatment. Actually the profession's case, strong though it is, does not look as overwhelming to the layman as it does to the doctor. Breach of contract? Few outsiders would accept the view that the Labour Government's acceptance of the Spens reports constitutes an automatic guarantee of doctors (and doctors alone) against suffering through inflation. Refusal of arbitration? There is less inconsistency than the B.M.A. imputes to him in the PRIME MINISTER's advocacy of arbitration in the shipyards and his denial of arbitration to doctors. For the doctors' claim is not against an industrial employer but against the Treasury, and, since the size of the claim is such as to affect the level of taxation, no Government who think it their duty to govern would willingly entrust the decision to an independent arbitrator. (How many of us, in Mr MACMILLAN's place and with his knowledge of the coming crisis in shipbuilding and engineering, and on the railways, would in fact have settled the doctors' claim first, or in full?) When the PRIME MINISTER expresses his faith in "some form" of arbitration he may feel that so far as doctors are concerned, he has provided the best possible form in the Royal Commission which is already at work. The fear that the terms of reference of this body might prevent its giving due weight to the Spens reports, and to their implications, is clearly removable; and the present Government cannot be accused of altogether rejecting negotiations if they argue that the time for attempting a lasting settlement is *after* the Royal Commission has reported. It is then—perhaps in nine months or a year—that the profession will be able to decide whether the suggested arrangements are satisfactory or whether doctors should withdraw from the National Health Service

---

[1] Outlined on p 697

[2] *Lancet*, 1957, i 31

[3] *Ibid* 1954 i 1277

The words "withdrawal from the service" are being used in two different senses which need sharp distinction The kind of withdrawal which we for our part think both mistaken and professionally wrong is temporary like the industrial strike, it is an interruption of normal work lasting only till one or other side gives way, and when directed against a Government it is an attempt to impose terms on the community by extra-parliamentary means But the same objection does not, of course, arise when withdrawal is not being used politically, and there need be nothing unprofessional in doctors leaving the N H S, either individually or en masse, provided their notice is sufficient and their decision is irrevocable As to the purpose of the operation, some people are now talking as though a little "direct action" will not only make the Government pay what is claimed but also make them change the service in some beneficial (though usually unspecified) way Others, who have disliked the N H S from the start, see this as the moment when a new MOSES should invite his people to follow him out of bondage Before accepting such an invitation, however, general practitioners may well ask for detailed information on life in the wilderness, and they should consider, soberly rather than in anger, the nature of their present discontent

Apart from the dispute about money, this discontent arises chiefly from a feeling that the relationship of doctor and patient is no longer what it was, and that organisation has made medicine less enjoyable than in the days of purely private practice, also that it favours mediocrity and impedes progress We may note, however, that in so far as this is true it is not peculiar to the British system not long ago an American authority was saying that insurance schemes in the United States have altered the relationships of doctors, patients, and hospitals, which are now on a less personal basis[4], and in a lecture to students another American teacher has been speaking of "present mediocrity" and a degeneration of motive in which "achievement becomes less impelling than security" Very possibly the capitation fee is not in fact the best means of paying the family physician[2], but even so, its disadvantages cannot all be laid at the door of our Governmental oppressors, since it is the method which the profession itself has preferred to maintain[5] Given a cessation of the cold war which has been doing so much harm to the service, profession and Government should be able to consider seriously together what alterations in such arrangements can and should be made That even without such radical alterations there are big opportunities for improving general practice within the service has been proved by the enterprising minority of family doctors who have latterly done so much to raise its standards and increase their satisfaction in their work

Meanwhile, exacerbation of the cold war must damage not only the service but—even more—the profession From deep conviction, the B M A s chairman of council ominously insists that, for the sake of medicine and our children, every practitioner must agree to withdraw complete unity and loyalty are essential[6] But, from conviction as deep, many will decline to support a course which, whatever its immediate rewards, cannot but be ultimately harmful Today the general public still pays the profession the compliment of seeing something amusing, because incongruous, in the action recommended by the B M A there can hardly be a doctor in the country who has not had to suffer the greeting of some humorist "Hullo doctor! You on strike?" But if current emotion prevails over traditional wisdom, and practitioners follow the fashion of industrial disputes, such action will never seem incongruous again, and one of our most valuable if least ponderable possessions will have been lost Instead, the real need now is twofold—that the Government should restore confidence in the Government and that the profession should restore confidence in the profession Only then will they be able to work together to the same important ends

Phosphatases and Prostatic Carcinoma

ENZYMES which split organic phosphates and are most active around pH 5—"acid phosphatases"—are present in many human tissues, but their concentration in the adult prostate is several hundred times greater than in other organs[1] This high prostatic level is not present before puberty, and has been demonstrated only in man and monkeys, and to a lesser degree in dogs, it is not found in cats, rabbits, guineapigs, or rats[2] In human seminal fluid, acid-phosphatase levels are even higher than they are in the prostate[2] The physiological function of this enzyme is unknown, but, as we noted earlier[3] the acidity which is most favourable for its action corresponds to that of the vagina at the time of ovulation The subject of prostatic acid-phosphatase levels in serum is complicated by differences in methods of assessing activity and in the range of phosphatases measured Not all of the acid phosphatase in the serum comes from the prostate Of particular importance is the red-cell acid phosphatase, the serum level of which rises sharply if hæmolysis occurs The method of ABUL FADL and KING[4] involves inactivation of this fraction, but not of the prostatic fraction, by formaldehyde ABUL FADL and KING[5] also reported the almost specific inactivation of prostatic acid phosphatase by L-tartrate—a means of differentiation which has been found to be of value[6] but has not yet been so widely used as their formaldehyde method

In 1938, GUTMAN and GUTMAN[7] described raised serum acid-phosphatase levels in patients with prostatic carcinoma, and their work has been confirmed and extended by many others[8–13] Using the formaldehyde method, MERIVALE[12] found that 22 out of 23 patients with carcinoma of the prostate had serum levels above 3 units per 100 ml, 15 of them above

5 units In contrast, of 101 patients with other prostatic or non-prostatic conditions, 19 had levels above 3 units per 100 ml, and only 5 of them above 5 units By the same method, WRAY[13] noted levels above 3 units per 100 ml in 43 out of 73 patients with prostatic carcinoma, but only in 1 out of 427 with other conditions Various explanations have been suggested for the normal levels often found in proved carcinoma of the prostate It is possible that "barriers exist in the normal prostate gland that prevent the escape of acid phosphatase into the circulation"[10] and that invasion or metastasis is necessary before the serum levels rise[2 8] Production of the enzyme may cease in anaplastic growths[2], and previously raised blood-levels may be temporarily much reduced during intercurrent fever[8] An acid-phosphatase inhibitor has been demonstrated in some cases[14] Whatever the reasons, normal serum-acid-phosphatase levels cannot be taken as evidence against a diagnosis of carcinoma of the prostate But levels between 3 and 5 units per 100 ml, by the formaldehyde method, should be regarded as suspicious and levels above 5 units as strong evidence for such a diagnosis Urinary retention,[13] prostatic massage,[15] liver disease, and Paget's disease of bone[4 11] may all, however, give rise to "false-positive" results The effect of œstrogen therapy on prostatic carcinoma with high initial serum-acid-phosphatase levels can be judged by following the return of these levels to normal[2 9]

A phosphatase active at an alkaline reaction is related to bone production[16] Raised serum-alkaline-phosphatase levels are found in many bone diseases, including secondary malignant disease,[17] and in obstructive jaundice[18] Workers who have studied alkaline as well as acid phosphatase in serum in relation to carcinoma of the prostate have generally found that alkaline phosphatase is sometimes increased but it is not of much clinical value[8] WRAY, however, lately recorded characteristic patterns of behaviour of plasma-alkaline-phosphatase levels after œstrogen treatment of prostatic carcinoma[13] When the plasma-alkaline-phosphatase value was initially normal, a rise started immediately after stilbœstrol therapy began After reaching a peak, the value fell to normal more slowly When the alkaline phosphatase was much raised at the start there was an initial fall coinciding with the start of stilbœstrol, but after a few days it began to rise again and reached a peak above its initial value within thirty to forty days Thereafter there was a gradual fall, as in patients with initially normal alkaline-phosphatase levels WRAY found these changes helpful in confirming the diagnosis of metastasising prostatic carcinoma, in indicating the presence of unsuspected secondary deposits, and in judging the effects of treatment In at least 1 patient, failure of the expected pattern to appear was followed by the discovery that the primary tumour was bronchial not prostatic Such findings, if confirmed, will provide a useful supplement to acid-phosphatase studies in the diagnosis and management of carcinoma of the prostate

University Apartheid

WHEN the United States Supreme Court decided in 1954 that, for white and coloured students, "separate educational facilities are inherently unequal," it was making an observation as relevant to South Africa as to the United States In the same way that the Jim Crow colleges and schools acquired an inferior status and a reputation for poor training, indifferent staff and inadequate funds, South African non-European institutions have been handicapped in comparison with those for whites, and neither schools nor colleges "for non-Europeans only" have reached anything like European levels At the "mixed" universities of Cape Town and Witwatersrand European and non-European students have been given opportunities that were as nearly equal as seemed possible For medical graduates, the rewards of qualifying may be less (African, Coloured, and European interns, for instance, working at the same hospital, are paid at different rates), but the degrees of all students are nevertheless equal These mixed universities have been a healthy feature of South African life, for they have provided one of the few social meeting-places for young men and women of different races A spirit of racial cooperation has distinguished these students from their contemporaries, white and black, of segregated universities in the country, and the main opposition to segregated university education comes from these universities and their graduates

When, in 1951,[1] the Durban medical school was established as part of the Natal University, it represented to some extent a compromise between mixed and segregated institutions Natal University had students of all races, but conducted parallel classes for Europeans and non-Europeans, thus accepting internal segregation In the hope of those who had worked for its establishment, the Durban medical school was to be "primarily non-European,' but not exclusively so The Union government, however, offered to take full financial responsibility for the school, and it made the condition (reluctantly accepted by Natal University) that only non-Europeans were to be admitted to the school, except when special permission was granted by the minister of education Moreover, to further the aim of segregation, bursary-loans were offered to medical students on the condition that bursars undertook to confine their practice to non-Europeans and to work only in areas approved by the South African government One of the government's objects in developing the Durban medical school was to enable it to remove non-European medical students from the mixed universities and offer them alternative places in Durban The minister of education specifically promised that the Durban school, though segregated, would be equal to the white institutions, and this makes developments at Durban of crucial interest to multiracial societies everywhere it provides one more experiment in segregated education

Men and women of distinction were attracted to the posts at the Durban school, partly because of its association with the university, partly by the promise of stimulating teaching and research in a non-European school All were completely determined that no inferiority in standards or status would be tolerated Natal University was closely concerned in the development of the medical curriculum, and a seven-year degree course was planned, with several interesting features The preclinical years include courses in history, sociology, psychology, and a language The department of social, preventive, and family medicine (sponsored by the Rockefeller Foundation) gives the medical student, throughout his last three years, practical and theoretical training in family practice, with all its social and psychological implications The medical school has encouraged interesting educational methods and research programmes relevant to modern medical education and to problems of health and disease in Africa The record of teaching and research in this young medical school has been outstanding But, perhaps because of the segregation policy of Natal University, the parallel classes, and the separate student representative bodies, the Durban medical school could not make the same contribution to better relations between the races as the mixed universities, though non-white students—African, Indian, and Coloured—enjoy the advantages of association in class and residence As a constituent of Natal University, and with its high academic reputation, however, the school stands out in South Africa as an institution for non-Europeans that is on a par with similar schools for white students This itself was a significant achievement

[1] Report on the Government's intended action to remove the Faculty of Medicine from the University of Natal Durban Medical School, March 4 1957

Unhappily, it is now reported that the South African government has decided on complete segregation for South African universities[2] It has announced legislation to close Witwatersrand and Cape Town Universities to non-Europeans, and the Durban medical school is no longer to be a constituent of Natal University Instead, the University of South Africa (at present a correspondence college) is to become the examining body for the medical school, and the minister of education will control its policy, including the appointment and discipline of its staff Members of the staff, it is said, will be subject to dismissal if they "publicly comment adversely upon the administration of any department of the Government " or if they are associated with propaganda calculated "to cause or promote antagonism among any section of the population of the Union against any other section of the population " or "to impede, obstruct, or undermine the activities of any Government department" Thus, the medical school will become a State department and the independence of its teachers will be destroyed The University Apartheid Bill provides for Bantu colleges for Bantu, Coloured colleges for Coloureds How this will be achieved in Durban is still not known Strong protests have come from many quarters, medical and academic, and the government's action, taken without consultation, is regarded as a serious invasion of university autonomy University independence has been much treasured, the more so in the stress of the complex South African situation And many hold that to alter the character of the medical school in this way is to break faith with staff and students

In South Africa, medical schools have evolved and developed in the universities and they owe their vitality to this association There is no parallel in South Africa to the medical school growing up around a teaching hospital, nor is there anything comparable to the Royal Colleges in this country In Natal, the association with the university has been particularly important, firstly, because its potentialities attracted staff of high ability, in spite of the restricted student body, and secondly, because a small staff and a small group of students needed all the stimulus and assistance that other specialists could offer Thus, the psychology course, spread over two years, is the best the university could devise for the needs of medical students, though on paper there is only one part time lecturer responsible for this course The University of South Africa is not comparable to a university in this sense, and there seems no doubt that to reduce the medical school to the level of a State department is to destroy its claim to equality with the other medical schools It will lose its university status and, as the published protests have made clear, it will lose the confidence of staff, students, and the medical profession Posts at a school thus debased and restricted are unlikely to attract teachers of standing

With Witwatersrand and Cape Town reserved for Europeans and the Durban medical school under the minister of education, South Africa achieves total segregation in the training of its doctors Many fear that the standard of training of the non European doctor will be lower than that of his white colleague, and the South African Medical and Dental Council, which has not so far been prepared to admit dual educational standards for doctors, will, it is hoped, stand firm on this point The South African government is clearly determined to impress its policy of racial segregation on every corner of the Union, and nurses have lately joined those who have permitted racial divisions to be made in their organisation There can be little hope of reversing this manifestation in Durban, but the Medical and Dental Council will be widely supported, in South Africa and in many other countries, if it continues to insist on the maintenance of high teaching standards Those in positions of influence in the medical profession in South Africa will, we hope, realise how much they stand to gain in the esteem of their colleagues all over the world if they speak out boldly against this attack on the freedom of university and doctor

Research Beyond the Tweed

THE Scottish Hospitals Endowments Research Trust administer a fund of well over £2,000,000, transferred to them from the endowments of the old Scottish voluntary hospitals The income from this sum (over £90,000) is used to foster medical research, and in their first report[1] the Trust set out their powers and duties and their approach to their functions Much care is taken to avoid duplication of work and the Trust keep in close contact with bodies making similar grants They hope that universities and hospitals will continue to finance research from their own funds, the Trust favour applications made after preliminary work has been done Major apparatus bought by grants remain the property of the Trust, to ensure that it is put to good use (elsewhere if need be) when the project for which it was bought has been finished The Trust do not finance the purchase of normal basic laboratory equipment Before making any grant the Trust consult the Scottish Advisory Committee on Medical Research The seven trustees, whose chairman is Sir John Maxwell Erskine, hope that Scottish people will remember the Trust when they consider donations or bequests for research

HUMAN ANTIHÆMOPHILIC FACTOR FOR THERAPY

We have known for a long time that classical hæmophilia is associated with absence of a factor normally present in human plasma In 1937 Patek and Taylor,[1] working in Boston, Massachusetts, obtained from normal human plasma a globulin fraction with enhanced antihæmophilic activity Work at the same school showed eight years later that the antihæmophilic factor was associated with fibrinogen,[2] and then, in 1946, that the factor could be separated from fibrinogen [3] It seemed as if the preparation of a dried frozen human antihæmophilic factor, readily available, after simple solution, for administration to the bleeding hæmophilic patient, was in sight But unexpected technical difficulties connected with the exceptional lability of antihæmophilic globulin, and causing unpredictable inactivation of the fractions, have prevented the issue of such a preparation so far For the treatment of hæmophilia we have had to rely on transfusion of fresh blood or, more recently, of fresh plasma quickly separated from the cells and frozen at –20°C Such precautions are necessary because antihæmophilic activity falls off rapidly in blood stored in the usual way at 2–4°C, it is reduced by at least 50% after twelve hours under ordinary conditions

In an effort to overcome this difficulty preparations of antihæmophilic factor from the blood of animals have been tested, and these can have high activity Macfarlane et al [4] used a bovine antihæmophilic globulin, Fraenkel and Honey [5] recorded the successful treatment of a wounded hæmophiliac with an antihæmophilic globulin prepared from pigs' blood But these animal preparations have a strictly limited value because they are foreign proteins and repeated administration soon leads to reactions that can be dangerous Accordingly the article on p 647 of this issue by Dr R A Kekwick and Dr P Wolf, describing preparation of an effective concentrate of human antihæmophilic factor, is of great interest, representing what we hope is the penultimate step along a surprisingly long road It is not quite the end, because their preparation still contains fibrinogen

Kekwick and Wolf point out that progress in the preparation of concentrates of antihæmophilic factor was much accelerated when adequate methods of assaying antihæmophilic activity were developed The thromboplastin generation test of Biggs and Macfarlane [6] was the first in the field, but Kekwick and Wolf prefer the method, recently described by Wolf,[7] which provides a simple numerical value related to the prothrombin conversion of recalcified plasma This method uses an artificial substrate, resembling hæmophilic plasma, which is prepared from the supernatant solution left after precipitation of fibrinogen and antihæmophilic globulin from fresh normal plasma By this method the level of antihæmophilic factor in fresh normal citrated plasma is 8–18 units per ml (average 12 5 units per ml), and in classical hæmophilia the level is usually less than 3 units per ml This technique enabled them to assay quantitatively the antihæmophilic activity of the concentrates Another technical advance that has helped this work is the refrigerated centrifuge, most of the manipulations involved were carried out at temperatures near freezing-point The final products were dried from the frozen state at –20°C and stored at this temperature The product Kekwick and Wolf have used has about ten times the activity of normal plasma, the protein content is about 2 2 g per 100 ml and the viscosity of an appropriate solution in distilled water is so low that intravenous administration presents no difficulties About 70% of this protein is fibrinogen, the problem of separating antihæmophilic factor from fibrinogen, and at the same time ensuring good recovery of an active material, has not yet been satisfactorily solved

They report results in 6 patients with hæmophilia, in 3, extraction of teeth was undertaken The volumes of antihæmophilic-factor concentrate used varied from 100 to 300 ml (corresponding to 1 to 3 *litres* of fresh plasma), and these relatively small volumes helped to avoid overloading the circulation Assay of antihæmophilic-factor activity in the recipient's plasma showed mostly a satisfactory rise after administration of the concentrate Not unexpectedly it was much harder to raise the patient's plasma-antihæmophilic-factor level when actual hæmorrhage was occurring, for example, in one incident where the concentrate was given to a patient who had alimentary-tract bleeding, 60% of the administered antihæmophilic factor was immediately used up

No resistance to this form of therapy has appeared so far, one patient had repeated doses of one of their preparations over five months But Kekwick and Wolf insist that there are still many difficulties We cannot, it seems, expect just yet to replace blood-transfusion by injection of antihæmophilic-factor concentrate in the routine treatment of hæmophilia Antihæmophilic globulin is susceptible to handling even at low temperatures All the steps of the preparation must be carried out aseptically to avoid final filtration, with its inevitable losses They point out, too, that the average hæmophilic patient who is bleeding requires a dose of antihæmophilic factor equivalent to 2 litres of fresh human plasma derived from about seven blood donations There are thought to be about 2000 hæmophiliacs in this country, and a single annual treatment for each would involve processing plasma from 14,000 blood donations Such a manufacture, they say, "presents a formidable problem, whose solution is not yet clear" Perhaps the best to be expected at present is that the special centres which undertake the care and treatment of hæmophilic patients will carry a small stock of the frozen dried antihæmophilic factor for emergency use, it keeps for several months Meanwhile, other tissue sources of antihæmophilic globulin are being explored, for instance, Nour-eldin and Wilkinson [8] have prepared from brain tissue antihæmophilic globulin which was free from fibrinogen

These special preparations of antihæmophilic factor are of value only to patients with classical hæmophilia, such fractions are useless in the clinically indistinguishable Christmas disease If, therefore, a patient with "hæmophilia" is admitted as an emergency case to hospital, and it is not known whether he has hæmophilia or Christmas disease, he should be treated by transfusion of fresh blood until the diagnosis has been clarified by the thromboplastin-generation test

BERYLLIUM POISONING

Poisoning by beryllium is rare in this country, but in the United States over 500 case records have been collected and are now available for study at the Massachusetts General Hospital Hardy [9] has used this unique material to investigate one of the most interesting features of the disease, its relationship to sarcoidosis—or, as some would say, to other varieties of sarcoidosis Acute beryllium poisoning has almost been eliminated by better protection of workers and it is only the chronic form that is likely to cause diagnostic difficulties Workers may be exposed to beryllium during extraction of the metal or production of its alloys, in the manufacture of fluorescent lamps and tubes, in atomic energy development, and in certain ceramic operations Beryl ore is not harmful, but beryllium itself and certain of its oxides and acid salts, especially the fluoride and sulphate, are toxic As in other types of sarcoidosis, the granulomas have been found in the liver, spleen, kidney, myocardium, skin, lymph-nodes, pleura, and lung, but no eye lesions, such as iritis and uveitis, have been reported, nor have lesions been found in the tonsils and parotid glands There are other differences from sarcoidosis So far no case has been found in the American records in which there was radiographic evidence of enlarged hilar nodes without abnormalities in the lung fields, nor have cystic changes been found in bones The prognosis of beryllium poisoning is worse than that of sarcoidosis Although there may be spontaneous remissions, some respiratory disability and radiographic abnormality persist The history of possible exposure to beryllium and the distribution of the abnormalities may make the diagnosis highly probable, but spectrographic or chemical detection of beryllium in the lesions is the only conclusive finding

Hardy points out that the term "berylliosis" is confusing It is an ugly word and can easily be corrupted to "berylosis," which is misleading, for it wrongly incriminates beryl as the toxic agent She suggests that "berylliosis" should disappear and that the disease should be called "beryllium poisoning"—a welcome suggestion

THE FLOPPY INFANT

A RECENT newcomer to the group of muscle disorders in infants is the congenital myopathy described by Shy and Magee[1] They describe a family in which there were five affected persons, four of them male, in three generations The abnormality was noted at birth, or within a few months, as hypotonia and weakness of the legs, and in one instance the mother said that fœtal movements had been less noticeable than during a normal pregnancy There was weakness of the proximal muscle groups, more severe in the legs than the arms, and this led to delay in walking In one patient the sternomastoids and orbicularis oculi were weak Unlike most myopathies, however, the disease was not progressive Biopsy showed aberrant fibrillary bundles in the centre of almost every muscle fibre, which Shy and Magee believe are characteristic in anatomical arrangement and histochemical reactions

This disorder must be distinguished from other causes of primary muscular hypotonia in infants, notably Werdnig Hoffmann's disease, in which muscular weakness affects particularly the proximal muscles and begins within the first year of life Though Werdnig Hoffmann's disease is also familial, it usually appears in siblings rather than in successive generations, and steady deterioration leads to death within a few years The primary lesion lies in the spinal cord affecting the anterior horn cells and ventral roots, and those who prefer pathological terms maintain that the condition should now be called "infantile spinal muscular atrophy" The other label which is attached to limp and floppy babies is amyotonia congenita No firm pathological basis has been established for this condition, and this is not surprising, for Walton,[2] who followed up 109 cases diagnosed at major hospitals as amyotonia congenita, showed that they represent a wide variety of pathological conditions He recommends that the term "amyotonia congenita" should be abandoned or used only to describe a clinical syndrome Nevertheless, 17 of his 109 cases resembled the condition described as amyotonia congenita by Oppenheim[3] There seems little reason, therefore, to abandon the original term, but the diagnosis should be made with great caution and should be followed up to make certain that an alternative diagnosis does not present itself—myopathy, polymyositis, cerebral palsy, mental defect, or skeletal or nutritional disorders To this list Chambers and MacDermot[4] have lately added polyneuritis, which they think was responsible for the picture of amyotonia congenita in 3 children they studied

None of these conditions is common Nevertheless it is important that they should be distinguished from each other, since, in some, treatment may considerably influence the outcome

GASTRO-ENTERITIS IN UGANDA

MANY doctors come from other parts of the Commonwealth to Britain for postgraduate training, and they welcome, among other things, the opportunity to meet specialists working with new techniques and to see other aspects of research As we remarked a few years ago,[5] this traffic is predominantly one way and there is much to be said for arranging matters so that more young British doctors can have the advantage of experience abroad, and more of them would be ready to go if they were sure that they would not thereby lose a chance of promotion at home and if they were helped to take their families with them They would learn much—perhaps not least to appreciate the difficulties that face some of their Commonwealth colleagues We would like to see an extension of the existing arrangements for exchanges of senior registrars with other Commonwealth hospitals, and we welcome, therefore, as a sign of the value of such exchanges, the recent paper by Luder[6] from Mulago Hospital, at Kampala in Uganda, for it springs from that hospital's association with the Hospital for Sick Children, Great Ormond Street

In an inquiry into the diarrhœa and vomiting syndrome in African children in Uganda, Luder analysed the result in 100 consecutive children admitted to Mulago Hospital Many were moribund on admission, and there was seldom a single cause They were treated by the unusual method of re establishing normal feeding as soon as the diarrhœa showed signs of diminishing, often two days after admission to hospital, and there was no intermediate stage of dilute feeding 29 patients were fed intravenously, but the mean stay in hospital in all 100 cases was still only just over five days Some children, however, were removed from hospital before they had been fully cured, and 12 died, 10 within twenty four hours of admission, which partly explains the extremely short mean stay in hospital Nevertheless, 60 of the children were well in three days

Todd and Hall[7] were the first to show, in a carefully controlled trial, the value of *chemoprophylaxis* of infantile gastro enteritis due to the specific serotypes of *Escherichia coli* More recently,[8] they found that *chemotherapy* was of little use in mild infantile gastro-enteritis, except when it was due to the specific serotypes of *Esch coli*, when it was of very definite value This finding emphasises the importance of looking for these organisms, if only to help the clinician decide which patients would probably benefit from antibiotic treatment Luder did not look for these serotypes, but it seems unlikely that they caused many of the infections he investigated the patients did not come from slums or institutions the course of the illness was shorter, and in 75% the fæces contained pus and blood, which are rare in enteritis due to *Esch coli*, but not uncommon in salmonella and shigella infections Cultures were made from only 76 specimens, and these were taken from rectal swabs, which many workers have found less satisfactory than fæces Luder does not say whether carrier medium was used to transport the specimens, or what interval elapsed between taking and culturing the rectal swabs, so it is hard to assess the importance of the information that only 9 shigella and no salmonella strains were isolated

One aim of Luder's investigation was to determine "whether clinical observation or simple clinical pathological tests, suitable for poorly-equipped tropical hospitals, would enable cases to be subdivided into groups with possible ætiological significance", and this question was apparently answered because simple pathological tests seemed to provide inadequate evidence to help his clinical judgment Though his work has produced some interesting data, the very fact that it was limited to simple clinical pathological tests has restricted its usefulness

ROVSING'S OPERATION

FOR nearly fifty years the place of surgical decompression in the treatment of polycystic disease of the kidneys (Rovsing's operation) has remained a controversial subject Variations in the extent and behaviour of the disease and the lack of reliable information about postoperative renal function have made the results hard to assess Moreover, for patients with advanced disease, the operation carries a high mortality In a recent review of 18 cases treated surgically, however, Yates-Bell[1] drew attention to the symptomatic improvement and prolongation of life that can be achieved In 2 of his patients it was possible to compare the beneficial effect of unilateral decompression with the deterioration in the other kidney (as shown by excretion pyelography) after periods of eleven and nineteen years respectively Several other patients' symptoms were relieved, and in some there was a transient reduction of hypertension The immediate effect of the operation on renal function, however, was always adverse, though some later improvement could often be expected For this reason, in Yates-Bell's view, surgical treatment has little place in advanced polycystic disease with severe renal failure and should be reserved for early cases and those in which there is pain or recurrent hæmaturia

The immediate and often dangerous deterioration of renal function which follows exposure of the kidney and decompression of the cysts has in the past been ascribed largely to postoperative œdema and subsequent fibrosis of the residual renal tubules A preliminary report by Patton and Bricker,[2] however, indicated that many of the cystic nephrons retained some function, and their destruction at operation may well contribute to renal failure This thesis has lately been extended by a thorough study of renal function in 4 patients subjected respectively to bilateral decompression, unilateral decompression, surgical exposure only, and conservative treatment[3] After decompression clearance values fell immediately and were still low at the end of a year, but there was no notable change after simple exposure or conservative treatment Bricker and Patton conclude that decompression is not a satisfactory means of improving renal function and may even do permanent harm

The place of Rovsing's operation depends, therefore, on the respective values of these clinical and laboratory studies, and each individual case must be carefully assessed Everyone agrees that advanced cases should not be operated on, but a reasonable argument may be made out for decompression in patients with satisfactory renal function who are having symptoms On the other hand, symptoms are often transient, though recurrent, and they often respond to conservative measures With regard to prognosis it is doubtful, in the light of laboratory and genetic investigations, whether surgical treatment can, in general, influence survival Inquiries into the familial disease indicate wide variations in its natural course, often apparently related to the average prognosis of affected members in the family concerned[4] Any apparent prolongation of survival by operation must, therefore, be considered from this aspect and preferably substantiated by serial tests of renal function The position is to some extent analogous to that of bilateral "staghorn" lithiasis, though slow deterioration of renal function is the rule in this condition, operation is often best avoided unless serious symptoms demand it

SOME QUESTIONS

AMONG the flying spray of political persiflage some important questions were asked, if not answered, in the recent debates on the social services, the latest of which is reported on p 690 Freed from party undertones and emotional overtones, they reflect the real difficulties which beset the Welfare State today Can we afford to spend so much on the social services? Does the falling value of money mean that we are in fact spending less on them? Has their proportionate share of the national income fallen? How should the money be collected? Should the contributor pay more and the Exchequer less? Should all benefits be freely given to everyone? Should some be reserved for those who need them most?

It is in their attitude to this last question that the Government and the Opposition differ most sharply The Government believe that our limited resources should be concentrated where the need is greatest Let us, they say, discontinue or diminish indiscriminate benefits, such as subsidies on bread, milk, and school meals, so that we may offer more help to the widow, the sick, and the aged, to guard against extravagance, let us put charges on prescriptions, to give priority to children and expectant mothers let us make some charge for dental treatment The Opposition reply that a benefit may too easily become a charity when it is in fact available only to the less fortunate A charge, like a subsidy, they point out, falls indiscriminately and clumsily on everyone Those on whom it falls too heavily, say the Government, may reclaim their money from the National Assistance Board For many reply the Opposition, this procedure is too complex, for many humiliating

On the other hand members of both parties were prepared to accept it as reasonable that the many who are at work should contribute substantially to the social services The latest increase is earmarked for the National Health Service, and it was suggested that this arrangement might in hard times prove a valuable shelter from Treasury economies But it would be dangerous if the Exchequer contribution came to be regarded as a constant, and expansion, and indeed maintenance, of the services came to depend on rising contributions The weekly stamp is a blunt tool. So long as every man pays the same, it is inevitably tied to the amount that the lowest wage-group can afford, and several Labour members suggested that a system of graded contributions might be worth considering

Lord Hailsham, among others, has lately said that the design of our social services is distorted because it was planned to mitigate the hardships of the past rather than to meet the difficulties of the present Certainly inflation today is a more urgent threat than unemployment The cost of the Welfare State is higher than we expected and the taxpayer is hard-pressed But the nation's future depends on the education, health, and security of its citizens, and they in turn will probably depend on our finding the right answers to some of these questions

ORGANISATION IN GENERAL PRACTICE

Success of a Shift System

P M HIGGINS
M B Lond , M R C P
GENERAL PRACTITIONER, RUGELEY, STAFFS

THE cost of building and the restriction of capital make it essential, in planning a group practice or health centre, to study those designs and methods that allow more work to be handled without *proportionately increasing* the amount of space required Improvements in organisation and administration may serve this end so well as to affect considerably the planner's basic conceptions of what is needed

The traditional routine of general practice has been modified in many places and in various ways, but in most practices, for a large part of the working day—perhaps six hours or more—the surgery premises are unoccupied Where the surgery is part of the doctor's house this may be of little consequence, but in a group centre such a routine is wasteful of accommodation and staff

In 1954 our practice was faced with a sudden and unexpected increase of work As there was no prospect of enlarging our facilities correspondingly, the only solution was to improve organisation so as to make the best use of the existing premises

Our Patients and Our Surgery

In 1953 the practice consisted of four partners and an assistant One of the partners was almost wholly engaged in a small community of about 1800 people, while the others looked after about 10,500 patients in Rugeley itself and the surrounding area In that year a group centre was opened to serve this population An existing building was adapted to make a waiting room and office, and a lavatory and three consulting rooms were built on at the rear

While this work was under way a National Coal Board estate was constructed in the town Tenants began to move in during 1954, and by the end of 1955 there were 15,132 patients in the practice—an increase of just over 2800 But the increase in work was out of proportion to the numbers the new patients were 21% of the total practice, but they accounted for an average of 26% of the new calls (table I), and men from the new estate made 42% of the total male attendances (table II) Though another partner joined us, the practice and its facilities were greatly overburdened At each surgery the waiting room was full, the queue often reaching the doors An hour and a half before the evening surgery started, the waiting-room would begin to fill, and by 5 30 P M there might be 50 or more people waiting During 1955 there were 43,253 attendances at the surgery, on a Monday evening 130 or 140 patients might attend

To deal with this situation separate clinics for children and expectant mothers were held during the afternoons and an appointments system was started Similar arrangements have been successful in other practices, and they helped us too But the root of this problem was how to enable more than three doctors to work at each surgery session The simplest solution—to build one or two extra consulting rooms—had two disadvantages (1) the considerable capital cost, and (2) the administrative awkwardness of enlarging, in a linear fashion, the existing building The alternative solution—to work a shift system —would not have these disadvantages and would, moreover, spread, instead of concentrating, the work-load As we could not get permission to extend the premises, the first solution was in any case impossible, and we started a shift system on Nov 1, 1955

Surgery Hours

The final plan was that in the mornings—except on Wednesday and Thursday which were off duty days for some—two doctors would see patients from 8 30 to 10 30 A M and would then give way to two others who would work until 12 30 P M These four would see patients by appointment only, and, as it was then thought essential to make provision for casual attenders, without allowing them to destroy the appointment system, a fifth doctor was to be available from 9 to 11 A M to see such patients In actual fact, eventually all doctors saw patients by appointment, casuals were fitted in as necessary and proved much less of a problem than was feared

Dec 10	192	50	26 0

On Monday evening six doctors were accommodated in the three consulting-rooms—three from 4 30 to 6 P M and three from 6 to 8 P M , $10^1/_2$ surgery hours were thus available and 120 to 130 patients could be seen without strain On Tuesday evening five doctors worked similar shifts

The surgery premises were then in use during the following times

Monday
Surgery 8 30 A M –12 30 P M
Children's clinic 2–3 30 P M
Surgery 4 30–8 P M

Wednesday
Surgery 9–11 30 A M
Antenatal 2 30–5 P M
No evening surgery

Friday
Surgery 8 30 A M –12 30 P M
Antenatal } 2–3 30 P M
Children's clinic }
Surgery 5–7 30 P M

Tuesday
Surgery 8 30 A M –12 30 P M
Antenatal 2–4 30 P M
Surgery 5 30–8 P M

Thursday
Surgery 9–11 30 A M
Surgery 5–7 30 P M

Saturday
Surgery 8 30 A M –12 30 P M
No evening surgery

Thus on most working days the centre was being fully used from 8 30 A M to 7 30 P M or later During 1956 seven doctors, including a trainee assistant, were fitted into this scheme, using only three consulting rooms

TABLE II—SURGERY ATTENDANCES OVER THE PERIOD DEC 5-31, 1955 (COUNTED FOR 32 OUT OF A TOTAL OF 40 SESSIONS)

Total attendances	Total male attendances	New estate male attendances	% new estate
2773	1583	666	42

Staff

Under our old *régime* we employed two receptionists who had some help from the dispenser from the branch surgery Now we have an extra receptionist to work half time, but this addition has not been made solely because of extra work the dispenser has been freed *from some of her duties* in the main centre and the working hours of the staff have been organised into a more reasonable pattern The work has of course increased , in particular the number of telephone calls has gone up But the work is now better spaced , cards for most patients can be looked out before the surgery begins and the flow of patients is spread over a longer period The staff are now, however, almost wholly concerned with the reception and organisation of patients and have little time for other duties

Results

An immediate lightening of the strain and the burden of work was noticed by all the doctors, and it was at first put down to the season. Not until the end of the month were the figures produced, which showed that, in fact, in the first three weeks of November, the attendance-rate had been the highest for the whole year.

It is also worth relating the figures to the social classes in the practice population (table III). The main industry in the district is coal mining, but there are some light industries in the town mainly employing women. The practice also serves the agricultural area around the town. The occupation groups were derived from the 1951 census; the exact number of working males in the new population is unknown but it must be over 700, falling almost wholly into social classes III and IV.

To assess the success of the appointment system, a count was made of the number of appointments:

(1) By 3 P.M. for the evening surgery at 4.30 or 5 P.M.

(2) By the end of the evening surgery, for the next morning.

These criteria were fixed in order to rule out any possibility of the numbers containing any casuals turning up early to "queue", but, needless to say, these are minimum figures. By no means all the patients whose appointments were booked later than these times were casual callers who had to wait their turn. Particularly is this true of the morning surgery, because many more appointments for it would be made over the telephone before the surgery began. That few were casuals is shown by the numbers in the waiting room at the beginning of each surgery. From July to September there was an average of 62% appointments. Later weekly percentages were:

Week commencing Oct. 22—69% (total attendances 917)
„ Oct. 29—72% („ „ 855)
„ Nov. 12—73% („ „ 855)

(The figures for the last two weeks are not complete, relating to seven out of ten sessions in the week commencing Oct. 29 and eight out of ten in the week commencing Nov. 12.) Table IV gives detailed figures for the week with the largest number of surgery attendances (937)—i.e., that commencing Nov. 5.

TABLE III—SOCIAL CLASSIFICATION, RUGELEY AND STAFFORDSHIRE

—		Rugeley urban district	Administrative county (Staffordshire)
Total males (occupied and retired) aged 15 and over		3144	310 356
Social class	I	59	6040
	II	298	38 927
	III	1711	168 562
	IV	726	56 837
	V	350	39 990
Proportions per 1000 total	I	19	19
	II	95	125
	III	544	544
	IV	231	183
	V	111	129

TABLE IV—APPOINTMENTS FOR THE WEEK BEGINNING NOV. 5, 1956

—	—	Attendances	Appointments No.	Appointments %
Mon.	Morning	98	40	40
	Evening	116	111	95
Tues.	Morning	89	59	66
	Evening	92	81	88
Wed.	Morning	94	53	56
Thurs.	Morning	89	56	62
	Evening	113	105	92
Fri.	Morning	103	80	77
	Evening	52	38	73
Sat.	Morning	91	54	59

It is interesting to note that the evening surgeries appear to be much more fully booked, and over the four weeks Oct. 22 to Nov. 19 the percentage never fell below 74% and once was as high as 95%. The lower figures (ranging from 40% to 84%) for the morning surgeries may be due in part to the limiting effect of the criteria adopted; the true figure is almost certainly higher than this.

These figures show the extent to which patients made use of the system; we come now to examine its effectiveness in practice. The method chosen was to have the number of patients waiting counted every half-hour. Owing to staff changes and pressure of work these figures were collected for only fourteen sessions between Dec. 5, 1955, and Feb. 24, 1956. The maximum number waiting varied between 6 and 26, with an average of 11—except for one unusual occasion when it rose to 33 because one partner had fallen ill and another had been delayed half an hour in starting his surgery. When it is recognised that up to 140 patients were seen at one session, it will be seen how effectively the system worked. Moreover, the numbers waiting have to be broken down in three ways:

(1) They are waiting to see three doctors.
(2) Some are accompanying patients.
(3) Some are early for their appointments.

The effect of these last two factors became clear one evening when all three doctors were working to schedule, yet the waiting-room contained 12 people.

The maximum number waiting was almost always at its greatest at the time when the shifts changed, and we are now trying to diminish the effect of this by allowing a gap of 15 minutes at this time. Experience has shown the way to other improvements. The general rule is that 3 patients are booked every quarter of an hour, but allowance is now made for the individual doctor's rate of work. A profitable study could be made of the consulting-time needed by different groups; for example there is an impression that, on the whole, women patients need more

TABLE V—NUMBERS WAITING FOR WEEKS COMMENCING OCT. 22 AND NOV. 5 1956

Date	Day	Total attending A.M.	Total attending P.M.	8.30	9.0	9.30	10.0	10.30	11.0	11.30	12.0	4.30	5.0	5.30	6.0	6.30	7.0	7.30	8.0
Oct. 22	Mon.	89	125	2	10	12	8	15	5	0	0	6	7	5	9	12	9	0	0
	Tues.	90	116	1	4	13	12	14	8	1	0	8	4	9	12	15	–	0

	Sat.	91		0	3	9	7	0	0	–									

time than men and might therefore, with advantage, be given appointments towards the end of the surgery

More complete figures for the weeks commencing Oct 22 and Nov 5 are given in table v They relate to a period when, as will be mentioned, a fourth consulting room was in use, the figures of patients waiting must therefore be divided by four, and not by three

The main factor in this improvement has been the appointments system The chief effect of the shift system has been to spread the load Up to 30 patients are seen before the time when surgeries used to start (at about 9 30 A M and 5 30 P M), and this has diminished the bulge in the waiting room

The most significant evidence of improvement has been that we have now been able to reduce the size of our waiting room so that it now accommodates about 20, instead of 60, patients Not only does this make it a more attractive place, and lessen the risk of cross infection, but the space saved has been used to provide a new and more efficiently designed office The former office has been converted into a double purpose room which can be used either as a surgery or for dispensing and office procedures It has in fact been used as a fourth consulting-room with an adjustment of our shift system

No claim is made that the above represents an ideal arrangement, what has been done has been done under the pressure of events and in the face of severe limitations Further developments wait on better days and more spacious surroundings Until they come, purely administrative changes have enabled this practice to increase its facilities, to deal with an extra 2800 patients, and so to improve its organisation as to serve adequately a population of over 13,000 from a centre occupying approximately 1100 sq ft

I wish to express my thanks to the staff of the centre for their help in collecting the figures set out in this paper, to Dr Gerald Ramage, county medical officer of health, for providing the information in table III, and to Mr S Clewes, clerk to the Staffordshire executive council, for figures on the practice population

The members of the partnership are Dr B A Abbott, Dr P M James, Dr Stanley Dillon, Dr P J MacMonagle, and myself

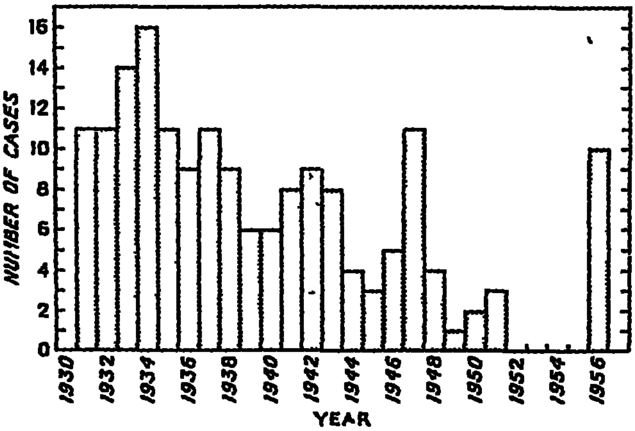
Public Health

"OPHTHALMIA NEONATORUM" AND MINOR NEONATAL INFECTION

I GORDON
M D Edin, M R C P, D P H
MEDICAL OFFICER OF HEALTH, ILFORD

IN Ilford, as the accompanying figure shows, notifications of ophthalmia neonatorum were steadily falling, until there were none in the four years 1952–55 In 1956, however, there were 10 (see figure) The disease notified is not classical opthhalmia neonatorum When the notification was received, each case was visited by a member of the public-health department, and by that time the condition had practically subsided No doubt many would have diagnosed the cases as "sticky eye", but why did the Ilford practitioners notify these 10 cases in 1956, and none in the previous four years, when undoubtedly they must have seen many cases of sticky eye? Presumably in 1956 they were stickier than usual

The 10 cases were notified by six different doctors, none notified more than 2 5 of the infants were born at home in different parts of the town, and 5 in hospital—four different hospitals, scattered over Greater London In 2 of the home confinements there was the same midwife, in the 3 others different midwives Hence there is no question of a local epidemic or individual reporting idiosyncrasies No publicity of any nature had been directed to this condition or its notification in the past few years locally



Cases of ophthalmia neonatorum notified each year in Ilford

I suspect that what is being notified is probably a mild staphylococcal infection Nearly all the extensive literature on antibiotic-resistant staphylococci refers to hospital practice, and half of these infants were delivered at home But, in resuming work in an infant welfare centre after some six years' absence, I have been impressed by the present extent of minor sepsis in the newborn—"sticky eye," mastitis (infective, not secretory), paronychia, blisters in the flexures, and discharging navels, and I get the impression that such sepsis is becoming as important as impetigo was in school children before the war

In New Zealand staphylococcal infection of the newborn and pemphigus neonatorum are now notifiable diseases,[1] presumably because New Zealanders are worried as to its prevalence May this have any relation to the system of paying practitioners according to the number of items of service they provide, which must encourage the use of antibiotics?

The national figures do not, so far, reflect any rise in the notifications of ophthalmia neonatorum It will be interesting to see whether the Ilford figures are an indication of the shape of things to come

Immunisation against Diphtheria

Observations in Heston and Isleworth have led Anderson[2] to conclude that in immunisation against diphtheria booster doses of antigen provide no significant advantage over primary immunisation only In a review of children born in 1941, 1944, and 1947, he found that of all who had undergone primary immunisation and had later received a booster dose 91 1% were Schick-negative, whereas of all who had undergone primary immunisation only 89 9% were Schick negative This difference being very small, Anderson concludes that, so long as the incidence of diphtheria remains low, reinforcing inoculations should not be undertaken

Population of England and Wales

The Registrar-General[3] reports that projections of the population of England and Wales show that, on certain stated assumptions, the total population will increase from 44,821,000 (as at mid-1956) to 45,569,000 in 1961, 47,423,000 in 1976, and 48,545,000 in 1996 In 1956 births registered exceeded deaths by 177,657 The corresponding increase for 1955 was 140,000, and the average increase for the five years 1950–54 was 107,349

In England Now

A Running Commentary by Peripatetic Correspondents

FEELING is running high among children throughout the country that so far there has been no reply to their plea that they should have an immediate rise to 1s for each extracted tooth A representative of the children said in London yesterday "There has been no increase in the agreed 6d bonus over the past thirty years During that time the price of cinema seats has doubled, bars of chocolate cost three times as much, and the advent of the new atomic weapons and Davy Crocket hats is placing enormous strains on our resources" The President of the Dental Practitioners' Union has said that dentists are unanimously opposed to a rise and that no interference from the State will be tolerated "Let us fight it out with the children," he said, "it is the only way to justice" Ministers are known to be deeply concerned that the situation should not worsen as there is clearly a risk that children will soon demand further rises in pocket-money, thus increasing the general inflationary effect on the economy "Let us arbitrate now—it will have to come to arbitration in the end," said the Minister of Paradontics last night He is confident that the Commission on Dental Awards will be able to produce a just solution for all

* * *

My dentist works at St Cecil's-in-the-South, across the way from our place, and, as we were students together in the high-and-far-off-times, my treatment is erratic to say the least When Conferences bow me down, it is too easy to mutter that old Bell won't mind, and send a message across In the same way he knows that to cancel my appointment won't lead to much heartache and waiting about Our average day seems to go something like this

I get a phone message at about 11 50 A M saying "Mr Bell rang but you were with the Professor and he says he's very sorry he won't be able to make your 12 o'clock appointment today but would you ring him back?" I ring back, and after a search they say "We're very sorry, but Mr Bell has just left and we don't know where he went Please may he ring you back?" I leave a clear account of my expected movements with both telephonists and tell them to flash my lights as well, but in the middle of the afternoon I absentmindedly settle in the one part of the outpatient department where the 3 per second flash does not penetrate "Oh *there* you are doctor, they've been ringing everywhere, there's a call for you from St Cecil's" The slightly hysterical telephonist says he couldn't wait any longer but would I ring back shortly By then Bell has been called to an unexpectedly fractured jaw, and is even now at the table I ask him to ring me back, and go home "Hallo, old chap," he says that evening over the phone "There you are at last, what was it you wanted?" "I don't want anything thanks, what did you want?" "Don't be silly," he says "You asked me to ring you back," "I know," I reply, "But you asked me to" "But you asked me to ask you to ask me to ring you back first!" he claims triumphantly "Nonsense, *you* started all this" I am emphatic on this point "Do you know, I do believe you're right now I come to think of it" he apologises "O.K, but what the hell *do* you want?" "Do you know, I'm not sure now" He is helpless with mirth "I believe it was to say I was sorry I couldn't make your appointment, yes it was Well, do *come over to* lunch tomorrow"

"Thank you," I reply "I'll ring you back"

* * *

Our hospital is a postgraduate teaching institution and it attracts a number of American nurses who pause there in their intensive global tour Our Senior Night Sister, seeing one of them on duty for the first time, remarked brightly, "Good evening, Nurse," to which the other replied "Hi," waving a hand in friendly greeting It was, accordingly, with some surprise that a recent arrival was observed to be polite and aloof to the point of coldness, adding a respectful "Sir" *to each* sentence Poor girl, we thought, she must have heard so much about the polite and formal British, and we gave her time to settle in At last my patience broke I had known her for some weeks, and one quiet evening I said "Please, Nurse, stop calling me Sir" She looked at me through those acutely angulated lenses and growled unexpectedly and quite without malice: "O K you lousy bum"

* * *

It was late and it was raining Bright shop lights added to the confusion of sodium street-lamps, zebra-crossing beacons traffic signals, keep-left signs, and all the other means of keeping the motorists' eyes off the road A little green Ford dragged itself reluctantly past the red light and shook bumpers with a big black one There this not unfriendly encounter might have ended, but for the long arm of the law

The hall of the stipendiary magistrate's court was crowded when, two months later, my solicitor looked gloomily at the notice-board and said "Yours is the last case of the day You won't get away before six Consider yourself lucky it's such a trivial affair If all goes well you might come off quite lightly Of course, you'll be fined, you know They all went up this year, so don't expect less than five guineas There will be costs on the top of that, they are often quite a tidy bit Of course, that's only for the first charge You'll probably get the same again for careless driving Let's hope they don't get you for dangerous driving—you could lose your licence for that Do you have to use your car in your work? Never mind, this should be quite a simple case Why don't you go inside and hear some of the *other* cases to take your mind off it?"

The first case was that of a young lady who had walked up and down the Strand a few times She was fined 40*s* The apologetic gentleman who next stood in the dock had failed to pay his taxes on time "Have you paid them yet?" the magistrate asked him Apparently he had "Then you must pay a fine of 10 guineas," said the magistrate The third prisoner was charged with stealing 6*d* It was not his first offence "What have you to say?" he was asked, to which he replied that he was very sorry and would take advantage of the earliest possible opportunity to repay the stolen sum "In that case, you shall be given your chance," he was told, "but you must first go to prison for five months"

I can't think why more people don't go into the legal profession Hearing cases at a magistrate's court seems to be rather like taking a G P surgery, except that you need think only half as hard, you get through the list twice as fast, and you are immune from litigation But I can hardly be said to speak entirely without bias

* * *

Last week I had to attend an important interview for a post in pædiatrics The prospect did not unduly worry me, though I was promised a gruelling hour's interview The night before the great event, however, I went through the interview in my dreams, and to my surprise it was so thorough that it included the *examination* of my *tonsils* One of them was said by the chairman of the board to be infected, and somebody else got the job

* * *

Why do doctors put strings of strange letters after their names? What use are L M S S A, M R C P, or D P M in helping a patient to find the type of doctor he wants? Why not initials to give a clue to the doctor's professional personality—e g, V S (very sympathetic), J H (jocular and hearty), or G G E (gives good examination)

* * *

The pioneers of America might be less surprised than is commonly supposed if they returned today The *spiritual descendants of Billy* the Kid, for instance, now show their killings by notches on the bumpers, are more often arrested by the sheriff, and are convicted in terms of blood-alcohol estimation and an inspection of brake-linings Methods of making tea devised at the Boston Tea Party are still in use to judge by the result Indian war-cries are still to be heard by *tuning* the radio to almost any station The standard crew cut of the American male shows only too well that the technique of scalping is not a lost art.

Letters to the Editor

FŒTAL AND NEONATAL ANOXIA

SIR,—While agreeing with almost all you say in your leader of March 16, I am unable to see the logic of your statement that the fact of infants being able to survive long periods of asphyxia without damage to the nervous system is "an encouragement to those who plead for more active resuscitation of the newborn" Presumably "more active" refers to positive-pressure oxygen We can all agree that if there is evidence of obstruction which cannot be relieved by posturing and nasopharyngeal suction, it is logical to pass a tracheal tube under direct vision and apply controlled suction But these *cases do not require artificial respiration*, the baby is capable of breathing, but breathing is obstructed The cases which are controversial are those in which intranatal factors (prolonged labour, low hæmoglobin in the mother, hæmorrhage, anæsthetics, analgesics, &c) have caused anoxic injury to the midbrain with failure of respiratory activity The baby is suffering from "white asphyxia" It is limp, pale, or cyanosed, and makes no respiratory effort In such cases it is doubtful whether the lungs can be made to expand and take up oxygen by positive pressures which do not also rupture the lung I have seen one case recently with bilateral pneumothorax following positive-pressure oxygen, this infant did not survive

No doubt this problem of the anoxic infant will become less urgent as all possible measures are taken to secure physiological parturition, but we are very far from this position at present and in the meantime it astonishes me that there is not universal acceptance of the value of intragastric oxygen Here is a method which is safe, which is available to any midwife if she is given the necessary equipment, and which secures oxygenation of the blood (enough to abolish clinical cyanosis) in perhaps 3 out of 4 such cases *It is a reasonable assumption* that this degree of oxygenation will prevent further cerebral damage and put the infant in the best position for spontaneous recovery of respiratory function Some experienced operators consider that there are times when intragastric oxygen fails to produce, or perhaps to maintain, a good colour in the baby, and when intubation will allow *bronchial* absorption of oxygen enough to save life, for this, relatively low pressures of oxygen are required This may well be the case, but laryngoscopy and intubation can be carried out only by someone medically qualified, with the necessary training and equipment More than three quarters of all deliveries are by midwives alone

Farnborough Hospital
Kent

D G LEYS

BRONCHIAL CARCINOMA

SIR,—We deplore the complacency of recent letters and wish to support Mr Vernon Thompson's plea (Feb 23) for a greater sense of urgency in the diagnosis of bronchial carcinoma and a greater awareness of its possibility in any doubtful respiratory illness Too often procrastination in actively making a diagnosis removes the chance of successful surgery Experience in Birmingham of 4103 cases recently reviewed [1] has shown that a successful excision of the growth by pneumonectomy or lobectomy offers a 21% chance of surviving five years, but only 12 2% had a resection This deplorably low figure was largely due to the fact that 63% of cases had inoperable growths or metastases when first seen at hospital Up to some point in their history, all growths must be essentially resectable Hence early recognition is vitally necessary

Most cases come to be examined on account of symptoms In 10% their first symptom has been of an inoperable nature (*neurological, metastasis*, swelling of the neck, &c) The others demand an X-ray of the chest since most (73%) are referable to the lungs That is where the "wait and see" policy, the "review in 6 weeks," the "unresolved pneumonia," and other futile reports spell death to the patient In a disease so common and with such prominence in the mind these days, it is extraordinary to us how reluctant *radiologists* and physicians are to consider the possibility of cancer There is no time to be lost—analysis of 1592 cases in 1950 [2] showed in untreated cases an average time from first symptom to diagnosis of 4 4 months and of life after diagnosis of 4 0 months Surgeons can hardly expect to cure their patients if they arrive only in the last stage of their illness

HOSPITAL MEDICAL RECORDS

SIR,—I wish to refer to a problem of some urgency regarding the fate of medical records in National Health Service hospitals

Hospital medical staffs of the National Health Service have recently been, or are likely soon to be, asked by their management committees to advise them on the question of keeping or destroying medical records This advice should be given with circumspection

Medical records—i e, case papers, reports, X rays &c —are, like other hospital records, Public Records, within the meaning of the Public Records Office Act This means that their preservation or destruction is subject to legal limitations and not to local or individual caprice In 1954 the Ministry of Health issued a circular (H M 54/47) to management committees informing them that at that time no records could be destroyed until definite permissive regulations had been issued These *regulations issued by the Ministry of* Health with the Public Records Office appeared in December, 1956 (*H M 56/103*), *comprising* a circular and a schedule of a list and particulars of certain classes of document accruing in hospitals and offices of hospital authorities not considered of sufficient public value to justify their preservation in the Public Records Office This deals with all manner of medical and hospital records many not of medical character

Under the terms of this last circular and the accompanying schedule, it is now permissible for management committees to destroy medical records of patients six years after their last attendance at the hospital in question except in the case of mental hospitals In the case of patients who died, the notes may be destroyed three years after *their death Both* circulars explain that this legislation is permissive and suggest that the records should in fact be kept for the longest possible time This point deserves great emphasis

The period of six years that is employed is probably inspired by legal considerations and from the medical viewpoint seems very short This is obviously so in relation *to the life time of* a child patient, or in respect of a disease liable to recurrence—for example, rheumatic fever It is also short in respect of a disease like disseminated sclerosis, which has a long extension in time

Aside from the welfare of the individual patient however, a considerable amount of genetic, statistical, and large scale social *medical* research must involve consulting records extending over a longer time than this Moreover, it is at least a tenable proposition that patients are entitled not to have their records destroyed at all Almost certainly they have no such right at present but whether they should not have one is worth consider-tion The provision of a medical dossier for all patients might be a proper and valuable feature of the National Health Service Perhaps a National Medical Archive Office storing microfilm copies of records is not an impracticable suggestion

---

[1] United Birmingham Hospitals Annual Cancer Report 1954 vol [illegible]

[2] Taylor A B Waterhouse J A H *Thorax* 1950 5,

Meanwhile, the practical problem of keeping patients' records revolves around the question of the space required for their storage The ideal way of keeping records is probably in their original and complete form Less satisfactory is to employ some selection of types of records to be conserved Microfilm records obviously save an enormous amount of space but the initial cost of the apparatus, as well as the continual employment of extra staff to operate it, represents a formidable financial burden, and such a solution might be more suitable to a Central Medical Archive Office than to smaller units such as hospital groups

In my view it is better that case-papers be kept intact and indefinitely and in their original form until some further consideration be given to this problem on a national scale It seems unsatisfactory that the fate of patients records should be decided at the level of local hospital management committees whose practice will certainly vary

INSULIN TREATMENT OF SCHIZOPHRENIA

Sir,—I should like to congratulate Dr Ackner Dr Harris, and Dr Oldham on their controlled study, a masterpiece of planning and execution, described in your last issue (p 607) Whether we like it or not, we shall have to accept their conclusion that insulin is not the therapeutic agent of the coma regime However, this need not sadden the old hands, it simply confirms that for getting there in medicine there is nothing like the prescription Sweat makes good mortar

Isleworth Middlesex.

H Pullar-Strecker

HEBERDEN SOCIETY

Sir,—Your report of March 16 (p 565) of the papers read at the meeting of the Heberden Society on Feb 22 contains a number of inaccuracies which we would be grateful if you would correct

First, with regard to the electrodiagnostic changes in polymyositis, no evidence of spontaneous lower-motor-neurone activity was found and it was the association of a high rheobase with an intensity-duration curve characteristic of denervated muscle that was of significance The characteristic electromyographic change was a predominance on volition of the short duration and polyphasic motor unit potentials typical of a myopathy with, in half the cases, the coexisting features of a neuropathic lesion—i e, long duration polyphasic motor unit potentials with occasional fibrillation potentials and positive potentials

Second, the paper on the electrophoresis of serum-proteins referred not as you report, to "glycoproteins," but to "mucoproteins" the fractions M_1 and M_2 of which form a part only of the α_1 and α_2 glycoproteins respectively Therefore, mucoprotein M_1 or M_2 should be read for α_1 or α_2 glycoproteins throughout your report While the spot shapes indicative of fraction micro heterogeneity were obtained after two dimensional electrophoresis, semi quantitative estimation of the two mucoprotein fractions were in fact based on a single electrophoretic analysis at pH 4 5

Finally, in the paper on sheep cell agglutination tests, the figures you report—e g, positive results in 48% of cases of lupus erythematosus—relate to those quoted from the world literature and were not the results obtained at this hospital upon which the paper was based More important however is the fact that not all of our lupus cases with positive agglutination with the supernatant had a positive result with the precipitate and as a method of distinguishing between rheumatoid arthritis and lupus erythematosus it was apparently reliable in the event of a positive agglutination with the supernatant Finally it was the cases of systemic lupus erythematosus without joint involvement that appeared to have a higher incidence of false positive Wassermann tests (especially the cardiolipin test) and it was in two cases, not one, of systemic lupus with positive agglutination tests that the activity lay in the β globulin zone

CIGARETTE SMOKING AT SCHOOL

Sir,—I was most interested in the article by Dr Parry Jones in your issue of March 23 I notice that he thinks his results might be abnormally high

I am at present conducting an investigation into the smoking habits of school-children in this county This is being carried out by means of an anonymous questionnaire following an explanatory talk to the pupils The eventual total number involved will be in the region of 9500 children between the ages of 11 and 16 and attending all types of school. Several months will elapse before the survey has been completed and analysed, but preliminary results indicate that Dr Parry Jones s findings are not in any way abnormal, and, in fact, some of my earlier findings show that the incidence of smoking is higher than he has quoted

RHEUMATOID ARTHRITIS WITH CHRONIC LEG ULCERATION

Sir,—It was not at all our intention, in our article of Feb 9, to suggest that varicose ulceration may not coexist with rheumatoid arthritis It would indeed be significant if two such common disorders were not often seen in the same patient We are naturally familiar with cases like the one Dr Rivlin mentions (March 9) in which, as he says, the ulcer obviously results from venous stasis

Our point is that in the cases we described we could decide that the ulcers did not so originate We need hardly detail the bed rest and ancillary treatment we gave for these ulcers except to emphasise that the methods we used were those by which we regularly heal stasis ulcers and that failure of these cases to heal was striking and at first unexpected

We agree with Dr Laine and Dr Vainio (March 23) that the L.E.-cell phenomenon is not specific, but we had more evidence than this Because of the clinical similarity of the cases, all showing skin ulceration with rheumatoid arthritis in the absence of vascular stasis we thought it right to group them together, and it then is seen that among six patients four had shown drug sensitivity, all had serum abnormalities four showed the L.E.-cell phenomenon, and there were many other features which taken together can all be covered by the diagnosis of disseminated lupus erythematosus and by no other single diagnosis

In describing these cases as "rheumatoid arthritis with chronic leg ulceration" we were careful to avoid calling them "disseminated lupus erythematosus with leg ulceration" and in our discussion we indicated the contrast between these cases and the more acute case in which the diagnosis of disseminated lupus erythematosus is more acceptable

In general the diagnostic criteria of disseminated lupus erythematosus cannot be precisely laid down If, therefore, we put these cases into the category of disseminated lupus erythematosus, it is only tentatively and with the realisation that further study may show this to be unsound Our chief purpose has been to indicate the need for further study

F RAY BETTLEY

A NEW CLINICAL ENTITY?

SIR,—Since the beginning of this year, I have seen more than 60 patients suffering from an infectious disease which has become epidemic It seems to fall into the category of benign myalgic encephalomyelitis, group II,[1] as seen at the Royal Free Hospital in 1955

In all cases there have been fever, generalised muscular aching, severe headache, and glandular enlargement In many these have been the only findings though the glands of the posterior triangle are most prominent, the occipital group is spared, thus distinguishing the illness from rubella and mononucleosis The Paul Bunnell test has been negative and the leucocyte count normal in those cases tested

Most patients present with respiratory-tract symptoms, unusual for this time of the year, and painful pharyngitis is common Aspiration pneumonia has occurred in a few

Serious complications are rare, but hepatitis, polyarthritis, and skin rashes have been observed

A recent development has been a recurrence of high fever during the apparent recovery stage

In all of the severe cases there is extreme weakness during the attack, sometimes with disproportionate depression It seems probable that a period of post infective debility extending over several weeks, may result in these patients

It has not been possible in a general practice to embark on laboratory investigation in all cases, but from the clinical standpoint, this is probably another outbreak of "a new clinical entity"

DENIS A HICKS

ÆTIOLOGY OF PRE-ECLAMPSIA

SIR,—Professor Franklin,[2] speaking on behalf of himself, Mr Sophian, and others, postulated that "toxæmia of pregnancy is, or includes, a progressively increasing tendency for the renal shunt to be brought into operation, and that fatal bilateral cortical necrosis is the maximal, irreversible result of this tendency" Mr Sophian, in his letter of March 16, has again claimed that the "primigravid uterus by resisting stretch imposes renal ischæmia, and that this change is responsible for the pre eclamptic syndrome"

Bilateral renal cortical necrosis is a very rare condition and there has only been 1 death from it in Bradford during the past ten years, during which there have been over 50,000 confinements It is almost invariably associated with toxæmic accidental hæmorrhage, and the most serious cases tend to occur at about the 30th week of pregnancy, and in multigravidæ Further, 20% of all cases of eclampsia occur in multigravidæ and 33% of cases of eclampsia occur before the 32nd week Pre eclampsia occurs frequently in multigravidæ and before the 34th week, and hydramnios in a single pregnancy is practically never associated with eclampsia These clinical facts do not support Mr Sophian's contention any more than do the findings of Dr Morris which were reported at the same meeting

The point I wish to stress, however, is that bilateral renal cortical necrosis occurs in infants and in non-pregnant women as well as in pregnant women, and does not cause the pre eclamptic syndrome[3] [4] The patient with this condition, who is doomed to die within a few days, may have a normal blood pressure and manifest no œdema She suffers initially from neither coma nor convulsions Conversely, some eclamptic patients secrete urine freely throughout the attack

At the same meeting I claimed that from 10 to 1[illegible] of all women were incapable of adjusting themselves adequately to the pregnancy lactation syndrome because of inherent defects, such as chronic nephritis, hypertension (whether revealed or latent), diabetes, and hypoplasia of the arterial tree, of the endocrine system or of the genital organs Adequate antenatal care, which involves weekly visits after the 24th week, can all but eliminate eclampsia and severe pre eclampsia, cut down the incidence of proteinuria, and delay serious symptoms until about the 36th week, when the infant is viable, but cannot decrease the incidence of hypertension

The nutritional-mechanical hypothesis thus postulates that serious disturbance of *la fixité du milieu intérieur* is prone to occur in "defective" women as a result of their efforts to adjust themselves to pregnancy, and can only be prevented by adequate nutrition, rest in bed and to a lesser extent by the use of hypotensive drugs

Bradford

G W THEOBALD

A STUDY OF WAKE

SIR,—Dr Cruden's "approach to the problems of insomnia" (March 16) calls, I feel, for much criticism Starting with an inadequate definition of sleep which he takes from an encyclopædia rather than a medical book he speaks of sleep and wake without mentioning "state of consciousness," which is the unifying concept for both phenomena A standard textbook[1] defines sleep as "a physiological depression of those parts of the brain concerned with consciousness, induced by the appropriate state of the reticulo-hypothalamic system" This definition would, clearly, do also for wake, if the word depression were replaced by "activation" Therefore Dr Cruden's calling wake "a temporary cessation of sleeping state" is rather nugatory and not exactly a "fundamental reorientation of thought"

Although I would not object to his statement that "We must be awake to study any problem, including that of sleep-wake," I cannot agree with him when he goes on to say that wake is taken for granted Much and well-known work (by Bremer, Hess, Magoun, and many others) has been done, *indicating* that the state of consciousness referred to as wake is the result of an activation directed to the cortex and produced by stimuli which are mediated chiefly by the brain stem reticular system, involving mostly the hypothalamus and the thalamus It is true, of course, that our present knowledge of the phenomena of consciousness, including sleep, is far from satisfactory, but this should not allow theories to be advanced uncritically

Next, Dr Cruden postulates that sleep is *the basic* state of life Such a postulate, if meant to be philosophical, should be dismissed as far too vague and dogmatic; seen from a strictly medical angle, on the other hand, it is quite incompatible with the accepted views on the attributes and propensities of life and its relation [illegible] with consciousness The main argument which Dr Cruden produces to prove orthodoxy wrong and support his postulate is "sleep" during the fœtal state and infancy Yet by calling the fœtal state sleep one is simply driven to unnecessary semantic confusion, because, logically, sleep should then also extend to the state of fertilised ovum!

Obviously, the application of the term *sleep* in its neurophysiological and psychological sense to the fœtus [illegible] becomes an absurdity The fœtus and the newly born are so immature neurologically and psychologically that their inert state can only be interpreted in structural developmental terms Increasing maturation that brings about cortical activity (and a differentiated state of consciousness) is followed also by inhibition Whether the latter is done by an inherent mechanism or by some chemical products of activity in general (as the earlier "hypnotoxin" theory had it) or by both has not yet been determined It seems, however, a fact that this inhibition is proportional to, and therefore a physiological requirement of, the amount of activity (not a "basic state of life," as Dr Cruden claims), while both are changing in duration as the developmental curve of human life takes us from the inertness of infancy to the full activity of adulthood and to the decline of senescence

[4] Theobald G W The Pregnancy Toxæmias London 1955 chap 30

[1] Brain W R Diseases of the Nervous System London 19

Dr Cruden's other postulate of "wake maintainers" is no more fortunate, for it is only another name for stimuli—impinging on the central nervous system at a time when the reticular activating system happens to be uninhibited

I dare say that doctors are aware of the importance of stimuli (physical and mental) in relation to going off to sleep, and treat their cases of insomnia accordingly, so I fail to see how calling these stimuli "wake maintainers," and claiming that wake is a temporary cessation of sleep, could alter the prospects of the unfortunate sufferers from insomnia

Reading the conclusion of the article I wondered whether the idea that arousal stimuli are "a threat to well-being" means, according to Dr Cruden's views, that "well-being" is sleep? This would, indeed, be an interesting point for discussion

Bethlem Royal Hospital,
Beckenham Kent

G M JACOBIDES

SIR,—In Dr Cruden's fascinating essay the conclusion is drawn by philosophical argument that "Wake" is the product of a Selye's "alarm reaction"

Approaching the subject from a practical angle, this view was put forward by Dr Galley and Dr Rooms as a result of their experiences with 'Viadril'[1] They suggested that a viadril analogue, waxing under the stress of waking and waning during sleep, may explain the mechanism of the alternating rhythm occurring in the sleep-wake cycle

The more our experience enlarges with this "bio-anæsthetic" viadril, the more we feel that by its administration we are producing a true sleep state

London S W 3

L H LERMAN

UNMARRIED PARENTHOOD

SIR,—Mr Mansfield (March 23) does little to solve the problem In this day when most people are calling for "their rights," the child-to be-born has only the "vagitus uterinus"—which, were it articulate, is perhaps too late But it has been aptly stated[2] that every child has a right to be conceived in love, to be born into happiness, and to be nurtured in security This is the basic teaching which must be given to married and unmarried alike, whether from school, youth club, church, or guidance clinic

Implicit in it is a condemnation of coition out of marriage, which may lead to unhappiness and insecurity and which is lust and not love Only within marriage is coition legitimate, not as Mr Mansfield suggests, more playful and lusty, but in the beauty of holiness Marriage between man and woman is a symbol of Christ and the Church[3] and anything intensifying that symbolic relationship is a sacred privilege

Raigmore Hospital
Inverness

WILLIAM HAMILTON

SIR,—In table VI of my article (Jan 19) I inadvertently transposed the number of legitimate and of illegitimate births in the group where social class was not stated Accordingly the last column of table VI should read, from above down 4, 1614, and 99 75

The corrected table shows that in nearly two-thirds of illegitimate births no information is available about social class Where social class is stated, the proportion of illegitimate births would appear to indicate the association to which I drew attention, but little weight can be attached to this since the omission of information may be highly correlated with social class

CYRIL GREENLAND

ALLOXAN AS A POSSIBLE THERAPEUTIC AGENT FOR PRIMARY CARCINOMA OF THE LIVER

SIR,—Two letters have appeared since the publication of our preliminary note on this subject on Jan 12

The remarks and suggestions of Dr Loxton (Jan 26) are most stimulating and indicate that he has appreciated fully, and apparently agrees with, our own orientation to the possible mode of action of alloxan We are not sure whether alloxan exerts its experimentally demonstrated effects in animals solely by virtue of the diabetes which it induces In fact there is considerable clinical evidence of a greater incidence of cancers in diabetics than in non-diabetic human subjects[1] In addition, maintained hyperglycæmia failed to develop in all but one of our cases with proven carcinoma, although there was quite strong clinical evidence and suggestive pathological indication that the alloxan injections had had some adjuvant effects on the liver cancers It therefore seems likely that alloxan may perhaps induce its anti-carcinogenic action by exerting a widespread effect, intra cellularly, on carbohydrate metabolism in *all* cells and perhaps especially on tumour cells—the latter believed to be more dependent on glycolysis It is at present our impression that the action of alloxan is transient, hence our recourse to repeated injections at intervals of about 2–4 weeks in all cases where follow-up was possible—a real difficulty in our work with uneducated Africans We have no information yet on the production of "oxidosis" by alloxan, nor have we tested the effects of dehydroascorbic acid as suggested by Dr Loxton We understand that other workers are investigating the action of this latter substance in experimental animals

As for the remarks of Dr Goldner (March 2)—we *were* unaware of the earlier studies on this subject, with some of which he was associated We have now consulted the first two of his references, the third not being available We feel that it is important to stress that following the 12 alloxan injections hitherto administered by us (repeated injections in several cases), renal damage has occurred in only one of eight cases—all with primary liver cancers We did not induce any other untoward reactions (aside from transient flushing) by alloxan administered according to the method and dosage which we detailed previously We venture to suggest the following explanation of the results reported by Dr Goldner and others who attempted the use of alloxan on a limited number of cases suffering from various types of cancers (but none with primary hepato cellular carcinomas which may perhaps be particularly susceptible to alloxan)

1 The nausea vomiting, chilling, and cyanosis induced in some of their cases may well have been attributed to a pyrogen in their solutions and *not* to the alloxan, more especially since these reactions did not appear in *all* their or in any of our cases

2 They administered enormous doses of alloxan, much more frequently than did we—e g, 220, 400, and 950 mg per kg body weight in human cases, in one case four times weekly, as compared with our usual dosage of 100 mg and maximal 150 mg at intervals of 2–4 weeks Doses as large as those used by Goldner and his associates are well known to be severely nephrotoxic and hepatotoxic in dogs

[3] *Ephesians*, ch 5 p 25

---

[1] Glicksman A S Rawson R W *Cancer*, 1956, 9, 1127

3 The ineffectiveness of alloxan on the cancers in their cases, and the occurrence of renal and hepatic damage, may also have been due to the very slow rate of administration of this drug—in their cases given over an hour or more, as compared to 1 *minute* in all our cases Duration of action of alloxan on islet cells is known to be very short lived—alloxan having a half life of only about 5 minutes in respect of its diabetogenic action Perhaps its action in intracellular carbohydrate metabolism generally may also be short lived, while hepatotoxic and nephrotoxic effects may perhaps occur only after long exposure to some other action of alloxan

In the light of the above, we do not think that Dr Goldner's evidence contradicts our findings or contraindicates further testing of alloxan in the treatment of carcinoma in man—especially if our dosage and method of preparation and administering alloxan are strictly adhered to, and if urine and blood are examined for evidence of renal damage before treatment On ethical grounds, the consistently hopeless prognosis, at least in our cases justifies almost any therapeutic measure, which holds out *any* hope of improvement Moreover, Sir, further studies—both clinical and experimental—in our laboratories clearly indicate certainly the theoretical and possibly also the practical value of alloxan therapy for understanding carcinogenesis We have now treated a total of eight patients In two of these, in whom hepatic pain was so severe as to require the use of analgesics, this symptom disappeared promptly and completely in both within 24 hours of the first alloxan injection In four cases the grossly enlarged liver diminished in size—in one by three fingers' width—within a fortnight of the first injection, and without deterioration in the clinical condition during this period Finally, our preliminary experimental observations in rats indicate that the metabolism in the ciliary body of alloxanised rats is influenced by feeding butter-yellow and also that the carbohydrate content of the benign hepatomas (preceding true malignancy inducible by butter-yellow in rats) seems to be different in alloxanised as compared with control rats These experimental findings suggest that the effects of alloxan on cancer induction or tumour growth may perhaps not be attributable solely to its diabetogenic action via the pancreatic islets, but possibly to some more subtle and diffuse effect on the carbohydrate metabolism and thereby on protein synthesis in all cells to a varying degree, but especially in carcinoma cells Experimental and clinical investigations on the actions of alloxan in carcinoma are being continued in our laboratories and hospital

THEODORE GILLMAN
MICHAEL HATHORN
N McE LAMONT

SIR —I found the observations of Professor Gillman and his colleagues stimulating Dr Loxton's comments on alloxan and cancer of the liver were also very interesting He was referring to Warburg's discovery that, in cancer cells, respiration is decreased and glycolysis increased alloxan may be able to block the main pathway—glycolysis—from which cancer cells derive their free energy and thus retard their growth

Dr Goldner has referred to earlier trials of alloxan in cancer

I should like to report my own observations on 2 patients treated with alloxan They were selected in the course of experiments designed to increase resistance to cancer growth or to reduce its invasiveness They were given repeated injections of alloxan but in smaller doses than those of Gillman et al Alloxan failed to induce diabetes and there were no obvious clinical signs of hepatorenal damage Of interest also is the post-mortem report in one case by Dr J C Burne

"Liver subcapsular adenocarcinoma, central congestion of lobules Bronchial lymph node papillary adenocarcinoma Pelvic mass papillary adenocarcinoma in wall of large intestine Spleen nothing abnormal Pancreas *considerable postmortem autolysis*, but no obvious hydropic or other change in islets

"No obvious degenerative changes in malignant cells, but mitoses scanty compared with those seen in operation specimen"

These findings suggest that tumour growth may have been retarded, and that abnormal carbohydrate metabolism can be associated with cancer

Bexley, Kent

W GROS

CHRONIC BRONCHITIS AND SMOKING

SIR,—As one who was fortunate enough to attend the N A P T symposium on chronic bronchitis, recently mentioned in your columns (March 16, p 593), may I draw attention to one considerable omission in the otherwise excellent series of papers? There was virtually no mention of cigarette smoking—one of the major ætiological and/or exacerbating factors

A N A P T pamphlet on chronic bronchitis describes smoking as "a very pleasant social habit" Medically, such a description is misleading, to say the very least, socially, it is just not true—as anyone will agree who considers the atmospheric pollution, litter, fires, and financial hardship it produces "It all depends which end of the cigarette you are on," as one of my friends aptly put it

Leicester

J P ANDERSON

BIRTHDAYS OF SPASTICS

SIR,—Dr Bevan (Feb 16) divides his sample of 62 spastics into three groups (table I) and notes that "The largest numbers were born in the period June to August (25)" He is *statistically* correct in suggesting that "This difference hardly seems to be a matter of chance" for $\chi^2 = 11\ 38$ and $P = < 0\ 01$ However, he may be *logically* incorrect if the three group division was made *after* he examined the distribution

TABLE I—MONTH OF BIRTH OF 62 SPASTICS

Month of birth	Observed	Expected	χ^2
XII, I II III	10	20 68	5 52
VI VII VIII	25	15 51	5 81
IV, V IX, X, XI	27	25 85	0 05
—	62	62 04	11 3

TABLE II—MONTH OF BIRTH OF 209 SPASTICS

Month of birth	Observed	Expected	χ^2
I	20	17 42	0 38
II	15	17 42	0 34
III	17	17 42	0 01
IV	21	17 42	0 74
V	20	17 42	0 38
VI	19	17 42	0 14
VII	16	17 42	0 12
VIII	21	17 42	0 74
IX	20	17 42	0 38
X	13	17 42	1 12
XI	12	17 42	1 69
XII	15	17 42	0 34
—	209	200 04	6 38

In our series of 209 spastics which were taken from a larger series of 448 cerebral palsy children, the months of birth were randomly distributed throughout the year (table II) for $\chi^2 = 6\ 38$ and $P = 0\ 90$

OBSTETRIC FLYING-SQUADS

SIR,—I have read Professor Nixon's letter in your issue of March 16.

I should like to point out that the rules of the Central Midwives Board do not prohibit the administration of ergometrine with the crowning of the head by midwives in domiciliary practice.

Central Midwives Board
London S.W.1

ARNOLD WALKER
Chairman

SIR,—As one who has for seven years worked among unurbanised tribal Africans in the Belgian Congo, I may perhaps be permitted to comment on Dr Grantly Dick-Read's statement last week that postpartum hæmorrhage is almost absent in uncomplicated labour in such a population. This is definitely not the case.

Such well-recognised predisposing factors to postpartum hæmorrhage as multiparity, anæmia, and multiple pregnancy are commonly present in these people. Every year we admit to the Baptist Mission Hospital at Bolobo, Belgian Congo, a number of women who have been reduced to a severe degree of anæmia by postpartum hæmorrhage.

I would agree with Dr Dick-Read that much serious postpartum hæmorrhage is due to faulty midwifery. It is difficult to imagine conditions under which more faulty midwifery is practised than among primitive Africans. In the area where I work, bearing down in the first stage is universally encouraged by ignorant village midwives. If the placenta does not separate, indiscriminate traction on the cord is practised, and where delivery is delayed interference of the most appalling kinds is indulged in. From experience I can assure Dr Dick Read that Africa is not the obstetric Utopia he imagines it to be.

Stoke on Trent

J. T. GRAY

EFFECT OF QUINIDINE ON POTASSIUM FLUX

SIR,—In their preliminary communication (March 16) on the effect of quinidine on potassium flux Dr Kärki and his colleagues state that at 37°C "the metabolic processes which drive Na^+ out of the cell and which raise the concentration of K^+ within the cell were active."

Since quinidine is a cell poison, we would expect quinidine (and probably most cell poisons) to have an unfavourable influence on such metabolic processes and to retard the re-entry of K^+ into the cell. It seems premature, however, to conclude that "this finding makes it seem likely that the action of quinidine is due to a reduction of the permeability of the cell membrane to potassium."

Rotterdam

C. K. V. v. DOMMELEN

FRACTURES OF THE FEMORAL NECK

SIR,—The review by Dr Murray and Mr Young (March 23) of the management and results of fractures of the femoral neck is a valuable presentation of fact, and as such is of great interest to all concerned with accident services. A study of the statistics gives a clear idea of the objects of the report, but note must inevitably be made of the high mortality-rate for both conservative and surgical treatment. The mortality for the total of 204 patients is 33%, for patients treated conservatively 48%, and for those operated on 26%.

Statistical comparison is often erroneous and in this instance may be invalid owing to unrecorded local factors, but on their face value these figures compare unfavourably with those from other clinics. The average mortality for 564 patients treated surgically, collected from the literature was 16.8%.

It is surprising to find that these authors conclude by saying that "... an emergency operation does not appear to be indicated ... the best time for it probably lies between forty-eight hours and seven days after the fracture was sustained." I believe the reverse to be true—that is that the operation should always be regarded as an emergency unless the patient is hopelessly moribund. It should be performed, not immediately, but within the first twenty-four hours.

Mervyn Evans,[1] reviewing the surgical treatment for trochanteric fractures in 101 patients from the Birmingham Accident Hospital, gave a mortality-rate of 10.9%. He wrote: "The best time to nail a trochanteric fracture is on the day of accident or on the following day, and where facilities are such that operation cannot be performed early it is probably better not done as a routine."

In my experience a careful anæsthetic and well-conducted operation, within twenty-four hours of injury, kills very few. It is often life saving and almost invariably promotes a marked improvement both in mental and physical health.

London W.1

PHILIP NEWMAN

GOVERNMENT AND PROFESSION

SIR,—Many of us are sick at heart. We feel humiliated, degraded. We are letting the country down when she can *least afford it*.

In the National press we are classed with the rest of the strikers. The engineers are striking in designated areas only, presumably where they can do most harm. Are they following our suggestions or are we following them? And make no mistake about it, it is a strike we are contemplating, and *we* are striking at the old and the sick. The British Medical Association say that we may tell the patients that the fees we charge should be reimbursed by the Government, but isn't this a gamble, and if it does not come off, who loses? Not the doctor, who has already pocketed his *5s.* or *7s. 6d.* Then about medicines. The patient takes his form along to the chemist, and it is the chemist, poor man, who has to take the risk. If he supplies the medicines prescribed by doctors outside the National Health Service, and does not charge the patient, he may not get remunerated by the State, and if this happens it will not take long to ruin a small man. Again, we are not the ones who get hurt, it is either the chemist or the patient.

Strikes come. Pay goes up. There is increase in the cost of production, and the cost of living goes up. Strikes again and the circle is complete. Cannot we who do not practise medicine only for a monetary gain but perhaps, too, because we love our work, be the first to stop this vicious spiral?

Exmouth

ARMOREL NETTELL

SIR,—If it is accepted that there is a just case for a rise in remuneration, then a settlement of this claim should be pursued. However, the very worse possible outcome of the present situation would be for a general rise of 24% in all our incomes, and I, and a good number of my professional colleagues, feel that our negotiators may be at fault in merely pressing the matter of remuneration whilst neglecting to stress the urgent needs for a reform of the service as a whole.

The needs for some reassessment and re-examination of the whole structure and organisation of the service after nearly ten years is very apparent to all those who work in it, and now that a Royal Commission has been formed it would be a pity if the opportunity for some such re-examination was missed.

Dealing primarily with matters of remuneration and speaking as a general practitioner, I would like to suggest a few possible measures that might be considered in any readjustment of our remuneration and as possible steps to improve standards and save public money. Before remedies can be discussed certain faults should be accurately defined.

(*a*) *Equal Pay for Unequal Work*

Apart from the present capitation fees which produce an increase in pay with the size of the practice, there is no grading of the services that are given by the doctor, and the size of a practice is certainly no criterion of the skill of the doctor or how hard he works

---

[1] Evans, L. M. *J. Bone Jt Surg.* 1951, 33B, 192.

(b) *Lack of Incentives*

There are at present no real financial incentives for improving standards It is all too easy for a doctor to do the minimum of work and get away with it

(c) *Lack of Supervision and Control of Standards*

Freedom of the individual to practise medicine according to his own views and principles must be jealously guarded and maintained, *But* at the same time since we are being paid *out of public monies to care for our patients* it seems only right that some steps be taken to ensure that the public is receiving a sufficient standard of medical care

At present, apart from very infrequent visits by the local medical officer of the Ministry and the rather ludicrous attempt at "inspection" of practices carried out last year (the results of which have never been published) by the local medical committees, there has been no activity to see that the lay public are being cared for properly

No one likes "controls" or "interference" but, on the other hand, there exist innumerable safeguards in hospital practice to see that suitable standards are being maintained and these are accepted as inevitable and reasonable interferences

If we are to receive increased remuneration then we should make it clear that we do not wish to receive it without at the same time endeavouring to remedy some of the faults of the present systems of remuneration and organisation, but the manner in which the claim is being pressed at present offers few such opportunities

Increased remuneration should be selective and in proportion to the work done Incentives must be provided for better work, and for the achievement and maintenance of high standards in general practice, and so must increased opportunities and scope for registrars in hospitals to climb the consultant ladder

Expenditure must be cut by carrying out a drastic re appraisal of the whole service and introducing some remedies to the ever-rising cost

Having noted some of the faults what of the possible solutions ?

The Royal Commission should have its terms of reference broadened to include this re examination of the N H S and its composition altered to include medical representatives

Regarding future methods of remuneration, I suggest that in general practice this should continue on the present basis of a capitation fee with the increases being obtainable by increasing opportunities and incentives, as follows

As a measure to improve standards and at the same time stressing the preventive side of general practice it is suggested that the practitioner is paid a fee of, say, 10s for regularly examining certain of his patients at certain specified periods and completing a form, as is the present case with forms for vaccination and *immunisation—at birth, in infants at* 1 and 3 years of age, in children at 5, 10, and 15, in adults around the vulnerable middle age, in the elderly at retiring age of 60–65, and in the aged at 70 and then at regular 6 or 12 monthly intervals In this way the average G P with a list of around 2500 will increase his remuneration by some £450

A much more delicate matter that is somewhat allied to "merit awards" might be the provision of some such system whereby the *practitioner who is providing a high standard* of care would have a scale of increased remuneration based on some agreed standards Thus, this scale might be based on the types of accommodation provided, on the organisation of the practice, including secretarial arrangements and record keeping, on the provisions for investigations, on group practices, and so on The manner in which this assessment is carried out would require further thought

To balance these increased opportunities for remunerative rewards there must also be some *saving* of money

With the practitioners undertaking an ever increasing proportion of routine school and infant examinations then eventually there would be no need for the present local infant welfare and school clinics This would be a considerable public saving

Prescribing costs must be reduced and methods for this purpose should be explored, beginning with an examination *of the whole principles of therapy* A good deal of unnecessary and irrational prescribing undoubtedly occurs, especially in connection with the newest and most expensive drugs and it might be well *to* consider the reimposition of some [illegible] on the excessive use of the broad spectrum antibiotics and the corticosteroids by the reintroduction of the restrictions to their use to certain specific diseases In hospitals junior residents should not be allowed to use these and other expensive drugs haphazardly without the specific permission of the consultant in charge of the case The Cohen committee might also undertake a stricter revision of the categories of drugs allowable on E C 10s

The hospital services account *for* the largest bulk of the service and it is here that large measures of economy could be considered It is surely reasonable to expect inpatients to contribute something towards their board residence Time and motion studies should be carried out by "business efficiency" experts *to* see where further cuts can be made in the administrative services, for it is quite common to hear of hospitals where the administrative staffs have increased by as much as 200% since the N H S began, without any increase in the clinical work of the hospital

I feel sure that I am expressing the opinions of many of my colleagues in *voicing* my concern over the course of the present disagreements between the profession and the Government and in deploring the stress that is being laid on remuneration and the lack of mention in official circles, of the needs for a complete reappraisal of the service

Beckenham Kent JOHN FRY

Parliament

The Government and the Social Services

IN opening this debate on March 19, Dr EDITH SUMMERSKILL criticised the Government's social policy on the grounds that it placed "an undue and increasing burden on those least able to bear it," and would, if continued, seriously weaken the country's social services As examples of this retrogressive trend she cited the reduction of the food subsidies, the increases in the price of school meals and milk, especially welfare milk and the increased prescription charges Yet though the Government had found time to introduce these economies, nothing had been done about the cost of proprietary drugs Doctors, for instance, were still receiving lavish samples of tranquillisers, a practice which she described as "not only extravagant but harmful to the whole nation" She considered that the Government's policy revealed a characteristic disregard of the needs of the poorest and a lack of coordination among its own departments

Mr DENNIS VOSPER, the Minister of Health, maintained that the Government's policy recognised that the amount which could be spent on the social services was not unlimited It was therefore important to eliminate waste and inefficiency and to make sure that the services were available to those most in need He suggested that the Opposition when they were in power had failed to establish these priorities and as a result spread their resources in social services too thinly

Turning to his own department for examples of improvements made possible by this realistic policy Mr Vosper said that the money allocated *to* hospital building would be £20 million in 1956–58 and he hoped that it would be possible to keep on allocating increased sums Waiting-lists, though still too big, had fallen from *526,000 in 1953 to 433,000 in 1956* This was due to a better use of beds, which was in turn dependent on better recruitment Every category of hospital staff had added to its members in the past few years During the past five years 2000 more general practitioners had joined the service, and, though no-one could be complacent about the shortage of dentists, the number now practising was the highest ever known The number of courses of dental treatment for 1956–57 for England *and* Wales was 11 million, 10% higher than the previous maximum before the introduction of charges

The cost of the whole health service for Great Britain for 1957–58 would be £690 million compared with £450 million in 1949–50 Much of this increase was due to rises in pay and prices but there would be an increase of 15% in real terms When the health service was started it was assumed that the Exchequer would bear 72 4% of the cost This year it was bearing 80 2% The proposed increase in the contribution would do no more than reduce the Exchequer percentage to 74 1 It would restore the contributory element by asking those who were at work to pay towards those who were not Surely this measure was fair and fell on those who could bear it The major part of the cost would still be borne by the taxpayer

Whatever the merits of the charges, Mr Vosper continued, the number of dental courses and sight tests were increasing to record levels It was too early to judge the effect of the change in the prescription charge December, 1956, compared with the previous December, showed a fall in the number of prescriptions of 25%, but January, 1957, showed a fall on the previous January of only 14% He doubted whether vast savings could be made through restrictions on proprietary preparations

He defended the increase in the prices of welfare milk on the ground that there was still a subsidy of 50% School meals, he thought, were still a good bargain at 1s , and here too it was surely good sense to reduce a general and indiscriminate subsidy to enable expansion in other directions

CONTRIBUTION OR TAX

Miss **Alice Bacon** pointed out that, though more money had been spent on the social services in the past few years, population, prices, and wages had been rising She reminded Members that the Guillebaud Committee had found that the cost of the National Health Service as a proportion of our national resources had fallen She was uneasy about the increase in the National Insurance contribution which was to be earmarked for the health service It seemed to carry an implied rejection of putting any further charge for this service on taxation Mr **Niall MacDermot** feared that if more and more people were to pay directly for the social services, and where the burden was too heavy turn to the National Assistance Board, the principle that the social services were a right and not a charity would be lost

Sir **Spencer Summers** thought that there was a danger that the ever-growing expenditure on the social services might, if uncontrolled, destroy the whole system He suggested that it would be reasonable to expect people to carry individually the normal running expenses of life, such as spectacles, but to join together to protect themselves from such hazards as old age or a serious operation Those who were receiving National Assistance, and indeed those who were just above the subsistence level, should of course be helped In the normal running expenses of life he included two children If the present family allowance for the second child in wage-earning families were discontinued, £55–£60 million would be available annually—perhaps to increase the allowances for the larger families or retirement pensions

Mr **Somerville Hastings** said that we had rightly decided that uneducated children and unhealthy people would be a national disaster and we had provided the social services to avoid this He was hopeful that when the Minister of Health could give more attention to the prevention of illness the cost of the health service might be reduced Dr **Donald Johnson** also put forward a claim for prevention, this time in the sphere of mental health, and asked for better domiciliary psychiatric services which, by keeping the patient in his home, would relieve and support our overcrowded mental hospitals

Mr **R P Hornby** pointed out that the proportion of the cost of the health service borne by public funds was greater in Britain than in any other country in Europe —90% compared with 32% in Belgium, 30% in Sweden, 30% in Denmark, and 20–25% in Norway He thought that the health service would gain if its demands were insulated to a greater extent from other demands on the Exchequer The illusion that the weekly stamp paid for the health service was dangerous It would be a gain if people realised what was involved in financing the service

Mr **William Shepherd** was willing to accept the increased charge for the weekly stamp if the prescription charge could be abolished Mr **James Griffiths** was also prepared to reconsider the insurance contribution In his view at *7s 5d* it had become a kind of regressive taxation putting the biggest burden on those least able to bear it The only person today who paid the full insurance contribution was the person who did not earn enough to pay income-tax The flat contribution had reached the stage when it was an obstacle to progress

Mr **John Boyd-Carpenter**, the Minister of Pensions and National Insurance, said that it was not the duty of any Government to preserve every detail of the existing system, but to modify it by expansion in some directions and reduction in others That was what the Government had been doing Examples of expansion were the increases in benefits for widows and their children and for disabled war-pensioners, and the improvement in the earning-limit for retirement pensioners and in family allowances In concentrating resources on the areas of greatest need the Government had taken into account that the bulk of the population had a higher standard of life than ever before

Turning to the health service he said that no Government was prepared to allow any particular service to impose an unlimited charge on the Exchequer If the cost of the health service must be limited there were three alternatives increased charges, a cut in the service, or the addition to the stamp Opinion could legitimately vary on the precise emphasis to be placed on one social service rather than another, but it was unfair and untrue to say that the Government had attacked the services as a whole The worst betrayal of the services and their beneficiaries would be to allow their foundations to be eroded by financial strain, too heavy a load of expenditure to accumulate, and the whole system to collapse

Foreign Patients and the N H S

On March 18 Mr **Gerald Nabarro** raised once more the question whether foreigners should not be charged for medical or dental treatment which they received under the National Health Service The cost of the service was now high The Government had been obliged to refuse an increase in remuneration to the doctors, to charge more for prescriptions, and to increase the weekly contributions In circumstance of this kind, he thought it scandalous that foreigners, and others who could well afford to pay, were treated free, at the expense of the British taxpayer

Mr **J K Vaughan-Morgan**, parliamentary secretary to the Ministry of Health, began his reply by pointing out that in this connection the term "foreigner" was not wide enough to cover these uninvited patients More exactly they were "non-residents," for the group included not only foreigners but also Commonwealth citizens, those from overseas Colonies, citizens of the Irish Republic, and United Kingdom citizens resident abroad but here on holiday or on leave The exact size of this group was not known One estimate was 1,200,000, and of these he understood that about 800,000 stayed less than six months and the average length of stay was only a fortnight Compared with the rest of the population that number was equivalent to about 12,000 bed-days at any given time and the total cost might be roughly estimated at £60,000 According to the London executive council's records, in any one quarter in the London area about 14,000 temporary residents were treated by general practitioners Of these fewer than a quarter were from abroad About 3000 were people from overseas Australia headed the list, followed by the United States, the Irish Republic, South Africa, and Canada On the basis of these figures the outside estimate of the cost of all non-residents using any part of the National Health Service was probably £150,000

Two kinds of treatment were involved First, there was accident or emergency He thought that everyone would prefer to continue on what has been called the Samaritan principle but he wished there was more reciprocity with other countries It was one thing to lead the world, but it was more consoling if others were following a little nearer behind But the crux of the grievance was of course the alleged use of the hospital services for expensive operations and the dental and ophthalmic services for costly work In practice steps were taken to see that these privileges were not abused and that those who came here for the express purpose of obtaining free treatment were so far as possible prevented from doing so All aliens coming into the country were interviewed, or could be interviewed, at the port of entry by immigration officers One of the purposes of the interview was to satisfy the authorities that they were not coming here to exploit the health service If there was reason to think that they were, those concerned were either not allowed entry into the country or the appropriate authorities were warned that they should be treated as private patients Last year about 1000 foreigners were dealt with in this way This procedure did not apply to Commonwealth citizens, but persuasion was used to achieve the same end, with some success If there was any exploitation of the dental or ophthalmic services we had to remember that a substantial charge was made and possible delays in securing and completing treatment really made it available only for long-term visitors But he agreed that the occasional loophole existed In short we had the informal machinery to prevent exploitation, but it was informal and incomplete To extend it would mean closer controls at the ports, imposing on doctors, dentists, and hospitals the unwelcome responsibility of discovering whether a patient was entitled to receive treatment, and bringing back the identity card at a cost of £1 million—surely a costly sledgehammer for such a small nut But the Government recognised the exacerbation which the present position caused Though the problem was not as large as had been suggested, and though the solution was not easy, it was much on their minds

Reciprocal Agreements

In a written answer the MINISTER OF HEALTH set out the following agreements under which British subjects may obtain medical treatment abroad

Multilateral Agreements

A reciprocal agreement is in force between the United Kingdom, France, Belgium, the Netherlands, and Luxembourg for giving medical treatment to indigent persons A convention extending this agreement to all members of the Council of Europe is in force between those countries which have ratified it (the United Kingdom, the Irish Republic, the Netherlands, Belgium, Norway, Denmark, the Federal Republic of Germany, and Sweden)

Bilateral Agreements

Under a reciprocal agreement with the Channel Islands visitors from the United Kingdom are provided with free inpatient and outpatient hospital treatment in Jersey and Guernsey and general practitioner services (excluding dental or ophthalmic treatment other than emergency ophthalmic treatment) in Guernsey

Agreements are in force whereby British subjects employed in France, Italy, the Netherlands, and Luxembourg who participate in the social insurance schemes of those countries can have their United Kingdom insurance taken into account in reckoning their entitlement, and that of their dependants, to medical benefit An agreement with Sweden, which is expected to be ratified shortly, entitles all British nationals in Sweden, including tourists, to use the Swedish health services A similar agreement with Norway awaits signature

Under Australian legislation free medical treatment is available to various classes of pensioners and their dependants A reciprocal agreement enables citizens coming from the United Kingdom to Australia to qualify for such pensions, and hence for free medical treatment, by virtue of their United Kingdom insurance

In general, the countries with which agreements have been made meet the major part of the cost of treatment

Homicide Bill

This Bill has been passed by both Houses without amendment It received the Royal Assent on March 21

QUESTION TIME

Remuneration

Mr MARCUS LIPTON asked the Minister of Health what consultations he was now having with the medical profession about the interim adjustment of pay for general practitioners—Mr DENNIS VOSPER replied I have nothing to add to the Prime Minister's reply on March 19 Mr LIPTON If no consultations are taking place and if arbitration is denied how [illegible] is this problem being dealt with? How long is this policy of drift and shift to continue? Will the right hon Gentleman take note of the fact that both the *Times* and the *Daily Mirror* consider that general practitioners have a legitimate grievance? Mr VOSPER My right hon Friend said he would make a statement in due course Nothing has happened since March 19 to affect that position

Bovine Tuberculosis in Scotland

The whole of Scotland is now within the area plan for the eradication of tuberculosis in cattle, and it is hoped that all the areas will be cleared by the end of 1959 At present [illegible] of the cattle of Scotland are in attested herds

Mental Nurses

On Sept 30, 1956, the mental hospitals of England and Wales had in their employment 10,709 whole time and [illegible] part time men nurses and 9649 whole time and 6740 part time women nurses The estimated shortage, in terms of whole time staff, was 2900 men and 4500 women

---

Obituary

HENRY ERNEST SIGERIST

M D Zürich, Hon D Sc Lond, D Litt., LL D, F R C P

Professor Sigerist died on March 17 at his home in the Swiss village where, since 1947, he had been working on his great new history of medicine As a historian he was unusual in his interest in the present His fine intellect enabled him to be a scholar, but his intelligence and his enjoyment of the world made him much more His approach was not that of the antiquarian he was always, he said, primarily interested in the general problems of medicine, investigating the past in order to get a clearer understanding of our own time and to help in preparing the future "To me the best way to understand a complex phenomenon has always been to study its genesis" He early recognised, too, that medicine is but one aspect of the general civilisation of a country—"that it is always determined by the general cultural conditions and by an underlying philosophy"

His own 65 years were eventful enough Born in Paris the son of a Swiss business-man, he was brought up in Zurich but at the age of 20 spent some time in London at the School of Oriental Studies After graduating in medicine at Zurich in 1917 he served as a doctor in the Swiss army, worked as a pharmacologist, and held a chair in his own university Then in 1925 came his first great opportunity, when he was invited to Leipzig to succeed Karl Sudhoff as director of the institute of the history of medicine [illegible] unique His career may now have seemed settled [illegible] in 1932, during a long and active visit to the United States, which provided material for his brilliant *American Medicine*, he was asked by William H Welch to succeed him in his chair at Johns Hopkins and take charge of the first American institute of the history of medicine Already he had shifted from French to German and the American appointment would mean adopting a third language—"which to a writer is a serious matter" But this was something that Sigerist, a good philologist, could take in his stride apart from his professional studies in Arabic, Latin, and Greek, he was at home in Italian and Spanish and by 1936 he could get along in Russian

In that year he was spending the second of two summers in the U S S R to collect information for his *Socialised Medicine in the Soviet Union*, first published

In 1937 and republished in 1947 This new book he regarded as a necessary complement to what he had written about America, for he had thought for some time that "the future of medicine will largely depend on what will be done in the United States and the Soviet Union" But, like many other visitors to the Soviet Union at that time, he perhaps allowed his sympathies to be engaged too strongly, and valuable though it is as an account of Russian medical organisation, his book too often leaves the impression that everything works as well as it is supposed to work The man who believed that in America medicine "has infinitely more to give than the people actually receive," and that medicine throughout the world is still in its first stage, was something less than fully objective in his attitude to a country where he saw science worshipped and "its progress is applied to life immediately for the benefit of the people" That is not to say, however, that he was unaware of the cost

During his years at Baltimore he visited not only Russia but also South Africa and India Of the Indian expedition W D-C writes

We had gone as members of a specially selected group of health experts from various countries to give evidence before the Health Survey and Development Committee (usually known as the Bhore Committee after its chairman Sir Joseph Bhore) which was planning the future health services of India Before giving our evidence we were all sent all over India to get an idea of the background of the committee's work by seeing the conditions and meeting the people of all kinds Sigerist proved to be a delightful companion on such a journey, full of interesting information, acute in his observations, penetrating though always urbane in his inquiries, with a delightful sense of humour and tolerant of those with slower brains than his own His intimate knowledge of Russia and its language provoked many questions from certain members of the committee attracted by what they had heard of Russian achievements, and I remember well Sigerist being asked on one occasion whether it was not true that the Russians had succeeded in a certain project He paused momentarily and than answered quietly "Yes, but at the cost of five million lives"

In 1947 after some fifteen years in America, Sigerist returned to Europe, though still linked to Yale University as a research associate with professorial rank. He had produced various "interim" books, including *Civilisation and Disease*, and *The University at the Crossroads*, but he longed to get down to what was to be his final work Unfortunately the plan was not to be fulfilled, and only the first of the eight volumes has so far appeared—his *Primitive and Archaic Medicine* Though he was able to produce his Heath Clark lectures delivered at the London School of Hygiene in 1952, illness increasingly interfered with his activities

Of this final period H E L writes

I had the pleasure of visiting Professor Sigerist last summer in the little village of Pura It was obvious that he was still physically weak after a cerebral accident some months previously, but the conversation flowed easily and he insisted that I should not go, as I intended, after half an hour

He spoke about his student days in Switzerland, his appointment at Johns Hopkins University and the influence he found there of William Welch He spoke about his work during the war when he built up some understanding of Russian medicine, and then ultimately of his return to Switzerland to do his 'serious work" For me, it felt like being taken into a dim room and then suddenly seeing it in a penetrating light which left me with a vivid image and a new appreciation This he did again and again that afternoon

Most of this talk was over tea It turned out that he was a connoisseur of tea, and we were now tasting from about a dozen little sampling cups On looking back now, I am sure that I was asked to stay probably because I did not ask for milk and sugar The only demand that he ever made on his students from Asia, he told me, was that they should keep him supplied with exotic teas But he also added 'The most interesting teas I buy from the shop in Piccadilly in London"

His serious work was the great *History of Medicine* of which he had completed the early volumes Although he knew that he would not live to finish it he felt that he had at least formulated the plans and laid the foundations His untimely death has left a gap in the ranks of men who are civilising the world

THOMAS GRAINGER STEWART

M D Edin, F R C P

Dr Grainger Stewart, consulting physician to the National Hospital, Queen Square, with which he had been actively associated for over forty years, died at his country house at Wantage on March 18, at the age of 79

The son of Sir Thomas Grainger Stewart, professor of the practice of physic at Edinburgh University, he was educated at Edinburgh Academy and Edinburgh University, where he graduated M B in 1900 After holding a house-physician appointment at Edinburgh Royal Infirmary he came to London and in 1902 was appointed house-physician at the National Hospital, where later he was successively resident medical officer and assistant pathologist before being appointed assistant physician in 1908 For a short time he was on the staff of the Metropolitan Hospital, and in 1909 he joined the staff of the West London Hospital on which he remained until 1937 He was also neurologist to the Central London Ophthalmic Hospital He obtained the M R C P in 1904 For his M D thesis in 1912 he was awarded a gold medal, and the following year he was elected F.R C P

During the 1914–18 war he worked at the Ministry of Pensions hospital in Hammersmith His association with this Ministry continued until a few years ago, when he retired from Queen Mary's Hospital, Roehampton—a hospital in which he was greatly interested, and where his experience proved invaluable in assessing neurological disorders associated with Service conditions At the National Hospital he became full physician in 1924 He was due to retire in 1942, but as many of his younger colleagues were on active service he went on working there until the war ended

Dr Grainger Stewart went to Queen Square at a time when great advances were being made in clinical neurology, and he made his own contributions to these, notably in two important papers written in collaboration with Sir Gordon Holmes , Their joint paper in 1905 on the Symptomatology of Cerebellar Tumours was a landmark in the diagnosis of destructive lesions of the cerebellum and the clinical differentiation between intra- and extra-cerebellar tumours This report was followed in 1908 by their joint paper on the connection of the inferior olives with the cerebellum in man In 1906 he drew attention in this journal to the occurrence of tremor in tumours of the frontal lobes He was joint author with the late W Aldren Turner of a Textbook of Nervous Diseases (1910)

F M R W writes

To an old house physician, and later, colleague of Dr Grainger Stewart at Queen Square, the news of his death brings back many pleasant memories of a high principled and unselfish man, a considerate chief and colleague, a sound clinician of the old school, a conservative in the best sense of that abused word, and a man conscious in his later years of having lived into an age he liked less and less

Haste was unknown to him, and slow in speech as in movement, his outpatient sessions and ward rounds were no brief events, but went on, regardless of the clock, until he had discharged his sense of duty to the task in hand The weekly pattern of notional half days that forms the chessboard upon which the modern consultant makes his permitted and allotted hospital movements could not have contained him, and had one, unkindly, explained it all to him and discussed its influence upon the life and thought of the physician of today, he would have been horrified

When in 1939 so many of his young colleagues left Queen Square for activities elsewhere, he quietly took on outpatient work again and so continued until their return, when, as quietly, he disappeared almost unnoticed from the hospital

Except as a young man he wrote little An excellent textbook of neurology written together with his senior colleague, Aldren Turner, did not have the success it deserved Indeed, after Gowers' classic text became out of date, the separate neurological text did not thrive in this country for very many years

Nor was he a notably attractive clinical teacher, and it may be said that his house physicians were the only real recipients of the great store of clinical knowledge and judgment that he possessed, and in these young men he inspired a deep affection One of his most distinguished pupils, Professor Monrad Krohn of Oslo, was amongst Grainger Stewart's warmest admirers and friends, and to have inspired this feeling in a neurologist of international fame, himself a brilliant writer and teacher of neurology, is perhaps an indication for the discerning of the qualities that Grainger Stewart so unobtrusively possessed

In 1922 Dr Grainger Stewart married Lady Playfair, widow of Sir Patrick Playfair, who survives him

FREDERICK WILLIAM PRICE

M D Edin, Hon M D Belf, F R C P

Dr Price, whose death we announced last week, served for many years as physician to the Royal Northern Hospital Though his chief specialty was cardiology, he had also gained useful experience in diseases of the chest while working at the Mount Vernon Hospital and the City of London Hospital for Diseases of the Chest But he will of course best be remembered by the famous textbook which is familiarly and respectfully known as *Price*

Lafayette

He was the son of William Price of Weston-Rhyn, Shropshire, and he was educated at Ruabon Grammar School, North Wales, and the University of Edinburgh After graduating M B in 1898 he held a house-appointment at the Edinburgh Royal Infirmary before coming to London to take up the post of assistant resident medical officer at the Brompton Hospital After some years as pathologist and registrar to the City of London Hospital for Diseases of the Chest he became medical registrar at the Westminster Hospital He was also at this time physician and pathologist to the Mount Vernon Hospital for Consumption and Diseases of the Chest To this period belonged his collaboration with James Mackenzie and Arthur Cushny in the research on the efficacy of drugs in cardiac diseases He also carried out independent investigations on the action of digitalis and aconite In his opening address to the Academy of Medicine in Toronto in 1912 he described some of this work

His growing reputation as a cardiologist led to his appointment to the staff of the Royal Northern Hospital, and of the National Hospital for Diseases of the Heart He was one of the first physicians to restrict his private practice almost entirely to diseases of the heart

His book on *Diseases of the Heart* appeared in 1918 and he contributed articles on his specialty to many of the well-known systems of medicine before his own appeared in 1922 In welcoming the first edition we said that "its place was in the hands of the practising physician," and for the past thirty years that is where succeeding editions have been The task of revision, as carried out by Dr Price, was arduous, for he was a painstaking editor, scrutinising and if need be modifying every page of every manuscript submitted Despite periods of serious ill health he was himself responsible for the first eight editions, often working in his study when he was too unwell to go to hospital or see patients

G G relates how Price used to go through a manuscript with a contributor

I had a great shock the first time, for the pages were full of corrections and a schoolmaster would have given me very few marks in composition He then proceeded to go through it line by line asking me exactly what I wanted to say and suggesting alterations which I usually accepted unless I expressed a different meaning He was always anxious to vary the words so that I should not have too much repetition Every now and then he would stop and say "Is this all necessary? I don't understand it" I used to reply "Yes," and perhaps give an explanation He would usually thank me and continue reading aloud The whole process took a long time, but he impressed his own style on the book and it was certainly easy to understand I believe he treated all the contributors in the same way and some were much annoyed Although I did not always agree with his corrections, I am grateful because I learnt a great deal from his comments His book has certainly fulfilled his ambition to be a credit to British medicine

In 1943 Dr Price married Miss Hilda Brown, of B[illegible] She survives him

A memorial service is to be held at All Souls' Church, Langham Place, W 1, on Monday, April 1, at 12 30 P M

ISAAC JONES

M D Melb, F R C P

Dr Jones, chief medical officer and consultant physician to the Metropolitan Police, died on March 24 at the age of 74

An Australian by birth and education, he graduated from the University of Melbourne in 1909, and later held the appointment of clinical pathologist at Melbourne Hospital After postgraduate study in Vienna, Berlin, and Paris he served during the 1914–18 war as a [illegible] in the R A M C On demobilisation he settled in London and for a time acted as deputy director to the medical unit at St Thomas's Hospital In 1929 he succeeded Sir Maurice Cassidy as chief medical officer at Scotland Yard From that date until a day before his death he gave unstinted service to the Metropolitan Police For this work, writes C M P, he was singularly well qualified by his vigorous personality and solid physique—in some degree developed by his Australian upbringing

An uncompromisingly robust and common sense attitude to clinical problems was associated with a deep knowledge of medicine especially in gastro-enterology Though not trained in psychology, he recognised its importance in a force which is exposed to exceptional strains and was most successful in getting many men back on to a level keel by his understanding. On the administrative side he was responsible for the establishment of a most efficient dental service To the police nursing home and the convalescent home at Brighton he gave unswerving support and cooperation The introduction of the National Health Service in 1948 considerably modified the medical control of members of the police He accepted the position and by tact and management continued to maintain contact and indirect control to a remarkable degree

At St Thomas's Hospital he made many loyal friends and exerted a powerful influence on the teaching of practical medicine to many generations of students But his main interest remained the welfare of the Metropolitan Police Though by inclination a confirmed countryman, he took, in the opinion of his less energetic colleagues, absurdly short holiday breaks By his devotion he won the confidence and affection of all ranks of the force—from commissioners to constables

Dr Jones was elected F R C P. in 1939 He leaves a widow and two sons

JOHN FREDERICK NICHOLL

M B Belf, D M R

Dr Nicholl, a senior cancer clinic associate at the Allan Blair Memorial Clinic of the Saskatchewan Cancer Commission, who died on Feb 25, at the age of [illegible], was born in Belfast He graduated M B from Queen's University in 1912, and after studying therapeutic and diagnostic radiology at University College Hospital, London, he was appointed senior assistant radiotherapist at St Thomas's Hospital in 1940 He took the D M R in 19[illegible] In 1950 he went to Canada as chief of radiotherapy and associate in diagnostic radiology at Victoria General Hospital, Halifax, Nova Scotia Four years later he joined the Allan Blair Memorial Clinic at Regina, [illegible] as radiotherapist but giving most of his time to the development and expansion of the radio isotope laboratory nt of newer techniques in this field Outside his work chief interest was ornithology and he was an enthusi- ic member of the Regina Natural History Society

He is survived by his widow, a daughter, and three sons

KATE FRASER

O B E, M D, B Sc Glasg, D P.H

Dr Fraser, who was the first woman to take part in e work of the General Board of Control for Scotland, ed on March 20 at the age of 79

She was born in Paisley, where her father Dr Donald aser was a general practitioner with a special interest mental disorders She took her B SC at Glasgow niversity in 1900 with special distinction in physiology d went on to study medicine, graduating M.B in 1903 ter holding resident appointments at the Bridge of eir sanatorium, the Crichton Royal, and the Southern unties Asylum at Dumfries she spent five years in neral practice in Glasgow With this she combined ork at the Royal Hospital for Sick Children and for the ovan parish school board Her interest in the problems mentally defective children grew steadily, and by 13 she was using Binet-Simon tests in their examina- on and assessment In 1913 she took the D P H, and in e same year she was awarded the M D degree with gh commendation for her investigation on syphilis a cause of mental deficiency She also studied the lationship of this disease to epilepsy The reputation hich she had already won was recognised by her ppointment in 1913 as a deputy commissioner of the eneral Board of Control for Scotland In 1935 she was ppointed a commissioner During her 33 years with the oard she had a long record of distinguished service r Fraser was responsible for the setting up of the x-Service Psychiatric After-Care Organisation in Scot- and She successfully urged the inclusion of the mentally andicapped in the provisions of the Disabled Persons mployment Act She was appointed C B E in 1945

After she retired in 1947 her wide experience of both ospital and community care of the mentally ill and the entally defective continued to be of great value While ost of her time was given to the work of the Scottish ssociation for Mental Health, of which she was a ounder member, she also served on various committees nd on the board of management of two hospitals and as associated as psychiatric adviser with the work of everal voluntary bodies In 1952 she was made an onorary member of the Royal Medico-Psychological Association, of the Scottish division of which she had een chairman for three years

T F writes

Dr Kate Fraser never seemed to become lost in the anonymity which so often invests the senior Civil Servant Everyone knew and respected her Yet she did not at all covet publicity, she was quiet, almost shy, fired with an obviously genuine interest in the welfare of the mentally afflicted which opened every door She had no enemies and when, on retiral, she went to live in Paisley it was just in the expected nature of things that she should continue to give freely of her wisdom and administrative sense to the Scottish Association for Mental Welfare and, in particular, to the notable work long carried on in Paisley in the interests of retarded children—a work which she had helped to pioneer Dr Kate Fraser had a unique place in Scottish mental health affairs and in Scottish affection, she will be greatly missed

A former colleague writes

In Kate Fraser's earlier years as a deputy commissioner roads and transport in the more outlying parts of Scotland (parts which she particularly loved) were less adequate than they later became In visiting patients under guardianship—work which she greatly enjoyed—she walked for miles over tracks, crossing bogs barefoot to reach some isolated croft Rather than return without seeing a patient in the most northerly island of the Orkneys, when the steamer could not berth because of the gale she let herself be thrown from the deck, as the steamer swept past in the heavy sea on to a pile of sacks on the North Ronaldshay pier and was storm bound on the island for some days The indomitable spirit that would not yield to bogs or gales was unquenched in her later years Difficulties were still to her a challenge and although latterly her physical appearance became fragile she was still possessed of drive in planning and vigour in attack Her strength of character was combined with a lively sense of humour, a happy friendliness, and a generous self giving To those who knew her well she has left the impact and influence of her great qualities of mind, heart, and spirit

MALCOLM CAMPBELL

M.A, M.B Edin, F R C S E

Dr Campbell died on March 13 at Droitwich where he had practised for many years as a consultant in rheumatology He was born in Edinburgh of Highland parents in 1873, and he graduated M A from Edinburgh University in 1895 and M B in 1900 After holding a resident appointment at the Royal Infirmary he took his F R C S.E in 1902. He spent a postgraduate year in Paris where he studied obstetrics In 1905 he was appointed as lecturer in obstetrics to the University of Edinburgh, and for the next three years he was assistant to Sir Halliday Croom

In 1908 Campbell settled in general practice in Brechin, but in 1914 septicæmia, followed by pyæmic joint-infection, laid him low for months He was sent to Droitwich as a patient and remained to practise For a time he was medical officer of health for the borough, but he turned more and more to the practice of hydrology, and his reputation in this specialty grew steadily In 1933 he was the British Government's representative in Toulouse at the International Conference of Hydrology, where his fluent French proved useful During the late war he was a president of the Vigornian Society, which met at the Worcester Royal Infirmary, and whose meetings were stimulated by the enthusiasm of the many American Army doctors who were stationed in the district before D day In the county he was a president of the Worcestershire Lawn Tennis Association and a vice-president of the Worcestershire Cricket Club He was also an expert gardener, with a particular care and affection for roses, sweet peas, and orchids

J W T. P writes.

One of Campbell's chief distinctions latterly was his brilliance as an after dinner speaker His Irving-like appearance, his easy style, and his choice diction never failed to win approval, and many who never knew him personally will remember him in this capacity But he will be missed by a great many people up and down the country, for under a somewhat austere and unapproachable exterior lay a kindliness which he was loath to show and an integrity which never wavered

His only son, Dr A M G Campbell, is a physician to the United Bristol Hospitals

GERALD STANLEY HOVENDEN

M D Lond

Dr Hovenden, who was a general practitioner in Barnes for over 50 years, died in Putney Hospital on March 14 at the age of 87 He was educated at the Whitgift School and qualified from Guy's Hospital in 1894, taking the M.D Lond two years later In 1900 Dr George Rodman, a cousin by marriage, who was in practice in Barnes and East Sheen, invited Gerald Hovenden and his twin brother to join him as partners. This they did and they remained in practice together till Dr Arthur Hovenden's death in 1946 Dr Gerald Hovenden finally retired only a few years ago

A colleague writes

During the late war, when his brother's health had broken down and his junior partners were called up, he managed to hold the practice together with only part-time assistance His appearance of being unhurried, even when he was doing four men's work, is still remembered by his patients He belonged to a generation when it was still possible for a general practitioner to claim that he was up to the standard of clinical assistant in the various specialties, and he was a skilled anæsthetist with chloroform and ether, he performed many Ts and As, he was a good dental extracter, he was a particularly good pædiatrician (he had been a clinical assistant at Great Ormond Street), and he had a large midwifery practice

His own family was the centre of his life and, through his kindness and understanding of human problems, he became the friend and counsellor to several generations of families in his practice His unsparing devotion to his patients' welfare inspired complete trust, and his gentle, genial manner and obvious enjoyment of his simple pleasures were typical of a man who was contented with his life He was also intensely interested in modern developments, both in medicine and in general—he was, for instance, a pioneer motorist He loved riding and, up to the late war, was a familiar figure in Richmond Park riding with his family He was a keen walker and dinghy sailor and enjoyed holidays abroad He was an excellent bridge and chess player, and the pleasure which he enjoyed from reading—in English, and in French and German—lasted till a few days before his death

He was married twice and had one daughter and three sons Two of his sons are doctors, one carries on his father's practice and the other is a surgeon commander in the Royal Navy

DESMOND WILLIAM GEORGE FARIS

O B E, LL D Malaya, M B Lond, D P H

Dr Faris, who till last year was dean of the faculty of medicine of the University of Malaya, died at Hove on March 20

He was born in 1901 and was educated at Thetford Grammar School in Norfolk and at Epsom College He entered the London Hospital Medical College in 1919 and took the Conjoint qualification in 1924 and the M B Lond in 1925 In the same year he was appointed as a medical officer in Malaya, and he took up his duties there in 1926

He soon began to make a special study of preventive medicine, and he took the D P H in 1931 His anti-malarial work and his keen interest in health conditions on rubber plantations and tin-mines earned high praise During the Japanese occupation, he was interned in Changi camp, but he did not allow this to break his spirit and made a useful contribution to the life of the camp under harassing conditions

After the war he was appointed chief medical officer of Singapore, and later he became principal of King Edward VII Memorial College of Medicine and, in due course, dean of the faculty of medicine in the University of Malaya In this post his past experience in public health proved a valuable asset He wrote the history of King Edward VII College and last year received the honorary LL D of the University of Malaya His death, so soon after his retirement, will be regretted by his many friends of all races in the Far East

JOHN GARVIN STEBBING

M B *Lond*

Dr Stebbing died on March 23 at the age of 32 Educated at Dulwich College, he began his career at Guy's Hospital in 1942, and he soon made his mark as a leader in work and in extracurricular activities After he qualified he held house-surgeon posts at Guy's and then for a year he worked in the physiology department Thereafter he spent two years on research of fundamental value in the department of surgery As H J B A recalls, "in 1953 Stebbing decided to go into general practice in Bermondsey and from then until his death he devoted his great qualities as a doctor to the care of his patients A certain shyness and a quiet manner concealed a strong character which was revealed to its full only during the last few years when, with superb courage, he carried on quietly with his work, knowing that he was suffering from an incurable disease, even though this work was interrupted from time to time for X-ray therapy Throughout his life he adhered to the rigid standard of conduct which he inherited from his father, the late Dr G F Stebbing, who, in his generation, also served the people of South London with such devotion and skill"

In 1935 Dr Stebbing became a member of the council of the Medical Protection Society He leaves a wife and daughter

ALEXANDER ALAN GUILD

M A Camb, M D, Edin, M R C P, M R C P E

Dr Guild, consultant physician and physician sup intendent of Lambeth Hospital, died in London March 9 at the age of 40

He took his preliminary medical course from C College, Cambridge, graduating B A with first-cla honours in the natural sciences tripos in 1938 He was a college prizeman He continued his studies at Edinburgh University, where he won medals in pharmacolo therapeutics, and public health, as well as a Murchiso scholarship in clinical medicine After graduating M in 1941, he spent six months as house surgeon at Edin burgh Royal Infirmary before he joined the R A M C He served with a field-ambulance in North Africa, Sicily Italy, Palestine, and Greece, and was mentioned in despatches He was appointed A D M S, Land Forces Greece, in 1945, and was demobilised with the rank of lieut -colonel the following year

After the war he returned to Edinburgh Royal Infirm to take a postgraduate course in internal medicine, befo becoming house-physician at the Southern Gene Hospital He passed the Edinburgh M R C P, wi neurology as a special subject, in 1947, and took t M D the same year In 1948 he took the London member ship and the same year he became clinical tutor to t medical unit at the Western General Hospital, Edinburgh In 1951 he was appointed physician superintendent a Lambeth Hospital He was one of the authors of t section on neurology in Davidson's *Principles and Pra tice of Medicine*

A colleague writes

Guild had exceptional ability and a profound knowledge *medicine In addition he had many interests outside medic* including music, art, and architecture He was widely re the classics, languages, and history He was a man of h principle and integrity who put his work before any ot consideration The welfare of his patients meant everyth to him and he spared neither himself nor his staff to attain th highest standard of treatment He took a special interes the neurological work of the hospital From his father inherited a judicial outlook, and he proceeded with th utmost caution in any matter which might lead to litigati In committee he could outline his policy with extreme clear ness, for he never seemed to lack the right phrase to descr the subject under discussion

His fellow consultants found him a loyal upright an friendly colleague His junior staff held him in high estee and learnt from him how to combine a good bedside manne with a thorough examination and investigation of a patient His ward sisters regarded him with affection and respe *He was a hospitable man and many of the staff were welcomed at his home When his house officers sought his guidance* in planning their future career he wrote them long and friendly letters

In 1951 Dr Guild married Miss Marion Bell, daughte of Sir Gordon Bell of Otago University, New Zealand She survives him with two young children

Notes and News

PLAN FOR WITHDRAWAL FROM N.H S

A LETTER addressed last week by the General Medical ervices Committee to all practitioners in the National Health ervice says that the British Medical Guild will take steps o obtain the resignations of all of them These will be put ito effect initially in selected areas, the number of which vill be progressively increased if need be

Practitioners in the areas selected will be asked to notify xecutive councils on July 2 of their intention to withdraw rom the medical list from Oct 2 They will not be asked o withdraw from the obstetric list This means that from ct 2, with the exception of maternity medical services, eneral practice under the National Health Service will ease in these areas

During October former N H S patients will be treated rivately but no private fees will be asked of them The ublic will be informed that doctors in these areas are anxious o give the Government one last chance to honour the promises nade to family doctors when they entered the N H S in 948, and that they are doing everything possible to avoid position in which their patients suffer financially Nevertheless, if the Government still decline to agree to a satisactory settlement or to arbitration it will be necessary after Nov 1 for general practitioners in those areas to charge their patients a standard token fee which it is recommended hould be 5s a consultation and 7s 6d a visit

Patients will be given receipts for these fees, and will be dvised to take them to the nearest National Insurance office in order that the Government may have an opportunity of efunding the sums involved Doctors will, of course, have liscretion to waive or modify these fees in special cases "

If a settlement is not reached, practitioners will later be ompelled to make full economic charges for their services

Practitioners who resign will be advised to issue prescriptions on private forms for the duration of the emergency It will be for the Government to decide whether they will refuse to accept prescriptions issued in this way

No National Insurance certificates will be issued General practitioners will issue their own private certificate forms

WORLD HEALTH ORGANISATION

TWENTY international experts met in Copenhagen last August to discuss research problems connected with the effects of radiation on heredity The committee was apparently concerned with only the peaceful uses of atomic energy Its report (which will be published within a few months, together with several specialised papers) says that "all man made radiation must be regarded as harmful to man from the genetic point of view," but holds that some risk must be accepted in view of the potential contribution of nuclear energy to man's social and cultural development

The report lists 13 fields in genetics needing urgent research if the harmful effects of radiation are to be minimised The effects of radiation are probably additive and may not be felt for some generations The radiation received by the gonads of the average individual is estimated at 2–5r in 30 years from natural sources, and 1–3r from medical X ray examinations, besides smaller amounts from other sources There is special danger in the increasing use of fluoroscopy by physicians who have had no formal radiological training

An accompanying paper by Prof R M Sievert, of Sweden, points out that many foodstuffs have lately been shown to contain artificial radioactive elements with a radiation level often greater than that of the natural elements, but the dose of radiation received by tissues from this source cannot yet be estimated Among the recommendations of the report are an increase in research and teaching in human genetics, the systematic registration of hereditary diseases, and the collation of data on fertility, consanguineous marriages and parental ages The group was much impressed with the hazards from man made radiation in medicine, industry, and experimental science

AN ACCOUNT OF THE HEALTH SERVICES

THE Central Office of Information has issued a reference pamphlet[1] describing the National Health Service and the various other public health services in Britain There are also chapters on medical research and on professional training The pamphlet presents much information in handy form

Royal Society

The 25 newly elected fellows of this society include Dr Saul Adler, professor of parasitology in the Hebrew University Jerusalem, Dr E C Amoroso, professor of physiology in the University of London at the Royal Veterinary College, Dr John McMichael, professor of medicine in the University of London at the Postgraduate Medical School, Dr Bruno Mendel, professor of pharmacology in the University of Amsterdam, Dr C L Oakley, Brotherton professor of bacteriology in the University of Leeds, Miss Charlotte Auerbach, D SC, lecturer in animal genetics in the University of Edinburgh, Mr J F Danielli, D SC, professor of zoology in the University of London at King's College

University of Oxford

It is proposed to confer the honorary degree of D LITT on Prof J F Fulton

University of Leeds

At a recent examination the following degrees and diploma were conferred

M D—Mary McMillan (with distinction)

M B, *Ch B*—C D Holdsworth P H Smith, Brenda Thiede (with second-class honours) J S W Brierley, Dorothy C Campbell J H Chippendale H M Chung, J E Cox Norman Cross Alan Darnborough, Eileen M. Gillespie Philip Goodwin L L Hemsy, P H Holmes David Jarratt, D T Jones, Vera E Lawton J W Lewis, Mohsen Mahloudji J W A Moxon D T Price, B E Roberts Audrey Sarfas, Margaret Sawyer Marion Sherman J N Smith R I Swires, R J Taylor D L Thiede F E Tomlinson Barbara F Turner R W Turner, Brian Whitaker, Dorothy M Wootton

D P H—E W G Birch Carl Burns George Cust J A G Graham John Harkness, M E O'Neill John Pemberton William Turner J A G Watson, Marianne H Witt

Dr G J R Soutter has been appointed lecturer in pædiatrics and child health

University of Birmingham

Prof Rustin McIntosh, director of pædiatric services at the Babies Hospital, New York City, will deliver the Leonard Parsons lectures at 4 P M on Tuesday and Wednesday, May 7 and 8, at the medical school His subject will be growth and development

Dr E H L Harries has been appointed lecturer in physiology

University of Dublin

At a recent examination for the D G O the following were successful

Nand Kishore Allahbadia B H Marten, Santosh Madan Santosh Khosla Saroj Kumar Ghosh Parkash Jit Kaur, Simon Froman

Royal College of Surgeons of England

At the annual dinner of the Faculty of Anæsthetists, on March 20, Mr Dennis Vosper, the Minister of Health, expressed his belief in the National Health Service The service would have been a bit different if it had been introduced more slowly, but once a big step forward had been taken it was difficult to take even a small step back. His job was to make the existing service work Replying for The Faculty, Dr Frankis Evans, its dean, spoke with pride of the research department, housed on the sixth floor of the Nuffield College This lusty infant was now assured of a healthy childhood, for industry and the great foundations had come to their help The director was unfettered by undergraduate or postgraduate teaching—a unique arrangement The next major requirement was a chair of anæsthetics, and for this a capital sum of £150,000 would be needed Sir Edwin Herbert replied for The Guests to a toast proposed by Dr John Gillies, who welcomed Mrs Pandit, the High Commissioner for India, as one "whose greatness—particularly as a champion of the underprivileged—is enhanced by her modesty"

At a meeting of the faculty, Dr H J Brennan (Manchester) and Dr H H Pinkerton (Glasgow) were elected to the board of the faculty for eight years Dr H C Churchill Davidson (St Thomas's Hospital) was re elected to the board for four years

St Mary's Hospital, London

Mr Edgar Lawley has been appointed chairman of the board of governors of this hospital in succession to Mr Anthony de Rothschild

Association of Clinical Pathologists

The general meeting of this association will be held at Torquay on April 11, 12, and 13

---

[1] Health Services in Britain 1957 H M Stationery Office Pp [illegible] 3s

Royal College of Obstetricians and Gynæcologists

At a meeting of council held on March 23, with Sir Charles Read, the president, in the chair, Mr J B Blaikley was appointed to visit New Zealand and Australia, and Prof T N A Jeffcoate to visit Canada and the Caribbean area, both as Sims-Black professors

Dr Claud Taylor will deliver the William Blair Bell lecture at the college, 58, Queen Anne Street, London, W 1, on Friday, May 24, at 5 P M He is to speak on mesodermal mixed tumours of the female genital tract Admission is by ticket only, obtainable from the secretary of the college

Hæmophilia Society

The annual general meeting of this society will be held on Sunday, April 7, at 3 P M at the Hospital for Sick Children, Great Ormond Street, London, W C 1, when Sir Weldon Dalrymple Champneys will deliver a presidential address

Naval Medical Compassionate Fund

A meeting of the subscribers to this fund will be held at 2 30 P M on Friday, April 12, at the Medical Department of the Navy, Queen Anne's Mansions, St James's Park, London, S W 1, to elect six directors of the fund.

Royal Institute of Public Health and Hygiene

Prof Philip Drinker, D SC, who holds the chair of industrial hygiene at the school of public health of Harvard University, will deliver the Harben lectures for 1956 at the institute, 28, Portland Place, London, W 1, on May 13, 14, and 15 at 5 P M He is to speak on air pollution and the public health

Wessex Rahere Club

A dinner of this club will be held at the Royal Clarence Hotel, Exeter, on Saturday, April 27 Membership of the club is open to all Barts men practising in the West Country Further details may be had from Mr A. Daunt Bateman, the hon secretary, 11, The Circus, Bath

National Spastics Society

Dr C P Stevens has been appointed director of this society

Dr Stevens is a former deputy senior administrative medical officer of the South West Metropolitan Regional Hospital Board, and his last appointment was as general secretary to the John Lewis Partnership

Stobhill Hospital, Glasgow

On March 19 Prof J W Howie opened a new department of bacteriology at this hospital Till now a disused Army building has served as laboratory The new laboratory has cost between £12,000 and £14,000, but in Professor Howie's view it is still not up to the standard appropriate to a hospital like Stobhill In preventing the spread of infection the public health service and the hospital both turned to the laboratory, and he suggested that it had therefore an important part to play in bringing them together

Drug Costs in New Zealand

Addressing the biennial conference of the New Zealand branch of the British Medical Association in Wellington, Mr J R Hanan, the minister of health, said the individual doctor was responsible *not only to his patient but also to the taxpayer* He was referring to the sharp increase in the social security pharmaceutical bill, which, he said, would exceed £2 a head of population this year In 1948 the total cost of pharmaceutical benefits was £1,558,000 In 1956 it was £4,039,000 "If the doctor is not going to consider the cost, with due regard to medical need first," Mr Hanan said, "then more controls will have to be established to keep the costs within the funds available"

Carlsberg-Wellcome Travelling Research Fellowships

The directors of the Carlsberg Foundation, in Copenhagen, and the Wellcome Trustees, in London, have decided to institute these fellowships, to encourage cooperation between Danish and British research workers in human and animal medicine

One fellowship will be awarded annually to a candidate from the United Kingdom for a year's work in Denmark and one to a Danish candidate for a year's work in the United Kingdom The stipend may range from £800 to £1200 per annum for whole time research Travelling and some incidental expenses will be provided in addition It is intended that the first fellowships will begin in September, 1957 Further information may be had from the scientific secretary of the Wellcome Trust 52 Queen Anne Street London W 1 Applications must be submitted before April 30

Faculty of Homœopathy

At a meeting of the faculty at the Royal London Homœopathic Hospital, Great Ormond Street, W C 1, on Thursday, April 4, at 8 P M there will be a discussion on the treatment of migraine

Association of Medical Microtomists

This association is to hold a demonstration of histological and allied techniques in the biology laboratory of Guy's Hospital Medical School, London, S E 1, on Friday, April 5, at 7 P M

Medical Inspectorate of Factories

Dr Sibyl Horner has been appointed Senior Medical Inspector of Factories in succession to Dr E R A Merewether, who will retire on Aug 31

Dr Horner, who studied medicine at the London School of Medicine for Women and St Mary's Hospital, qualified in [illegible] and took the D P H two years later She held a house appointment at Charing Cross Hospital and was an assistant medical officer in the school medical service of the London County Council before she joined the factory inspectorate During her 32 years service including 9 as a deputy senior medical inspector she has made a special study of industrial dermatitis

SOME ASPECTS OF INFLAMMATION AND INFECTION*

A H T ROBB-SMITH
M A Oxfd, M D Lond, F R C P
NUFFIELD READER IN PATHOLOGY IN THE UNIVERSITY OF OXFORD, DIRECTOR OF PATHOLOGY, THE RADCLIFFE INFIRMARY, OXFORD

IN 1927 Professor Kettle gave four lectures for the University of London on Some Aspects of Inflammation and Infection He would, I believe, have been fascinated, as I have been, by the changed approach to the pathogenesis of disease and of infection in particular, during the past fifteen or twenty years

In Kettle's lectures he looked at inflammation and infection from the viewpoint of the histopathologist who used experimental methods to clarify problems of morphogenesis, not from that of the experimental physiologist or the bacteriologist As he put it,

> "Without belittling the importance of bacteriology, it must surely be admitted that in any infective process, the microbe is only part of the story and not the most important part either, it is the reaction of the host to the presence of the microbe which constitutes the condition we have to study, and though regarded as an exercise in the science of botany, the intensive study of the tubercle bacillus has great merit, it will never solve the problem of tuberculosis"

Kettle showed that the inflammatory reactions to non-bacterial and bacterial agents were individually characteristic and that it should be possible to recognise the *nature of the irritant or the group of organisms involved, from the type of the reaction* He concluded his lecture with these words

> "It seems highly probable that a closer study of microbic inflammation will reveal specific tissue changes which may be of significance in the attempt to combat these infections If we understand exactly why particular bacteria makes good their footing in the tissues and how the tissues respond to their presence, it might be possible for us to devise logical methods of modifying or combating infection"

The Concept of the Biochemical Lesion in Pathology

This greater understanding of the nature of tissue reactions, that Kettle anticipated, is taking place, we are coming to realise that morphological changes are the resultant of alterations in cellular or extracellular function and that such function or dysfunction can often be defined in biochemical terms and in particular in terms of enzyme action

This change in thought cannot be attributed to any specific discovery or particular school, but it is probably the result of many influences all springing from an increased awareness of spatial and functional biochemistry One might try to trace the concept back to the iatrochemical pathology of the 17th century, or the serious attempts made by Virchow to interpret pathological changes in chemical terms, but in reality the germinal idea can be found in Gowland Hopkins's concept of dynamic biochemistry, admirably expressed in 1929 by Sir Rudolph Peters in his Harben lectures on Coordinative Biochemistry of the Cell and Tissues It is interesting to recall that Peters's thinking had been profoundly influenced by the work of Sir William Hardy, who, starting as a zoologist, in 1899 abandoned histology because he believed that any progress in our understanding of the structure of tissues must await advances in the knowledge of the molecules which composed them His own contribution was the development of colloid chemistry

In 1931 Kettle was puzzling over the pathogenesis of silicosis and carried out the classic experiment in which he showed that crystalline silica rendered insoluble by a coating of ferric oxide was harmless, and therefore that the lesion in the tissues in silicosis was not due to simple mechanical irritation but must be induced by the chemical action of a solubility product of silicon on the cells (Kettle 1932) In this same year Gavrilescu and Peters published a paper entitled The Biochemical Lesion in Vitamin-B Deficiency It had been known for some time that the opisthotonus and convulsions of rice-fed pigeons could be cured in a very short while by injecting thiamine, but in this paper Peters showed that, *in vitro*, thiamine had a specific action on the lowered oxygen uptake of avitaminous brain tissue, this was the first display of the pyruvate oxidase system of the brain, but it also formed the ground work for Peters's idea of the biochemical lesion in disease, which has inspired some brilliant research and I believe has a very wide application in pathology In essence, Peters's (1951) concept is that in many disease processes the initial lesion is a biochemical—usually enzymic—change in the tissues, and that this precedes any morphological alteration that could be recognised by ordinary microscopy, furthermore, these biochemical lesions may be reversible, and so from the point of view of therapy it would be desirable to detect them before they have disorganised the tissues

There has also been a change in bacteriological thought, so that toxins have ceased to be regarded as thaumaturgical poisons, which maim or kill their host, but as specific metabolic products to be defined in their action both chemical and pathological, the concept of competitive inhibition of enzyme systems has inspired chemotherapeutic research, and, although no agents comparable with the sulphonamides have been produced, metabolite analogues have been used with much profit in fundamental biochemical studies Advances in immunochemistry and the integration of the immune mechanism with protein synthesis has in some ways clarified and in some ways obscured the defence reaction

In the past few years, the remarkable developments in molecular biology have provided the morphologist with opportunities to see structural changes almost at the level of chemical reactivity But we must remember that at present it is *almost*, there is still a gap to be filled and structures to be resolved, which are smaller than 50Å, and it is in these dimensions that the problems of life are concealed

In this lecture I cannot present a formal review of inflammation and infection I would rather offer you a series of vignettes, and in many cases as in those delightful Victorian photographs, only one view will be apparent, the rest fading into a background of uncertainty

Phases in Inflammation

We can recognise four phases in inflammation—the initial reaction to injury, the early cellular and humoral reactions of the host to the injurious agent, the noxious effects of the agent, and the delayed or granulomatous reaction Naturally, it is not as simple as that, and according to the character of the noxa one or other phase may be inconspicuous or predominate

THE REACTION TO INJURY

Connective tissue is the commonest site for an inflammatory reaction to take place, and each of its components may influence the way in which the reaction evolves In essence, connective *tissue is a network* of scleroproteins and mucosubstances in which cells are lying, surrounded by vascular and lymphatic capillaries The intercapillary distance ranges from 50 µ in muscle up to 300 µ in fascia and tendon, these are seen to be of quite considerable magnitude when we realise that if a glucose molecule were the size of a man it would have to travel 50 miles to get from a capillary to a cell in the dermis

---

* From the Kettle Memorial lecture for 1956 delivered at the Wright Fleming Institute, St Mary's Hospital Medical School, London, on Nov 30

In this intercapillary space, there is an interlacing fabric of collagen bundles, of varying size, and an occasional elastic fibril, between the fibres are the connective tissue cells (fibroblasts, histiocytes, mast cells, and lymphoid cells) lying in the ground substance, which varies from a gel to a sol state and consists essentially of plasma—the extravascular plasma protein pool is about twice the mass of that in the circulation—with a considerable range of mucosubstances and collagen or collagen precursors in a globular or soluble form In the immediate vicinity of the capillaries there are numerous mast cells and mesenchymal cells, and the capillaries themselves are surrounded by a network of reticulin—a very stable form of collagen—and consist of endothelial cells separated by an intercellular cement and covered on the intravascular surface by a protein component derived from plasma, and perhaps, platelets

If we consider the basic type of inflammatory reaction—the triple response of Lewis, or a nettle sting—in Kettle's day it was delightfully simple, we had, in miniature, the classical physical signs of Galen, the alteration in capillaries and connective tissue as described by Addison, Waller, and Cohnheim; and an explanation (based on Lewis's work) that the initiating agent was a histamine-like substance

However, Kettle was not entirely content with this unitary hypothesis, and mentioned "that products of protein degradation are capable of producing vasodilation" as an illustration of the multiple factors that may be concerned in an inflammatory process

CHEMICAL MEDIATORS OF PERMEABILITY

These doubts appeared to be well substantiated when, in 1936, Menkin described a permeability factor "leukotaxine" which he had recovered from inflammatory exudates and had prepared in a pure crystalline form Although it was soon shown that Menkin's leukotaxine was neither pure nor crystalline, there is no doubt that his basic observation—that enzymic digests of fibrin induce some of the features of inflammation—which were soon confirmed, revived serious interest in the proximate mechanism of the inflammatory reaction which is still in full flood It has become clear, by the work of Spector (1951) and others, that a whole range of polypeptides of varying solubility, with physiological activities similar to those of leukotaxine, can be isolated from autolysing tissue or tryptic digests of plasma-proteins Furthermore, the inflammatory reaction to agents such as turpentine is not prevented by the use of anti-histamine drugs or histamine depletion

Lewis had shown in 1927 that the reaction to the nettle sting was indistinguishable from that produced by a local injection of histamine, but it was not until 1947 that Emmelin and Feldburg found that the nettle hair in fact contained both acetylcholine and histamine in sufficient amounts to account for the triple response and the itching and burning sensation In 1956 Collier and Cheshire reported that it also contains 5-hydroxytryptamine (5-H T, serotonin) and this may also explain the pain and itching, it is rather pleasing that Brittain and Collier (1956) have now detected a 5 H T antagonist in dock leaves So here we have the situation that the nettle sting, which thirty years ago appeared to be a perfect example of the simple reaction to injury, in fact introduces into the dermis a gamut of active amines which could fully explain the tissue changes without postulating any intrinsic tissue factors, and yet we have ample evidence of a whole range of tissue factors affecting capillary permeability

The tissue mast cells contain heparin, histamine, and 5 H T, and histamine and 5 H T are also present in the epidermis and in platelets Then there are the permeability factors in serum-globulin described by Miles and his colleagues (1955), this is a system of inactive precursors and inhibitors in plasma which is activated on dilution—that is to say, dissociation—or ageing and can increase capillary permeability in a matter of minutes, it is unaffected by anti-histamine drugs, but is antagonised by trypsin inhibitors, suggesting that it is a protease although distinct from plasmin Although Miles et al. had no definite evidence that their permeability factors played any part in the inflammatory reaction, Spector (1956) has demonstrated a very similar permeability factor and inhibitor in an experimental inflammatory exudate Macfarlane and Pilling showed, ten years ago, that the fibrinolysis system could be activated by dilution, and recently Lewis and Work (1956) have found that, in vitro, plasmin is able to release from plasma proteins substances which stimulate smooth muscle and produce vasodilatation similar to, if not identical with the polypeptide known as bradykinin which is generated from plasma by the action of trypsin or snake venom Armstrong, Keele, and their co workers (1957) have found in inflammatory exudates a pain producing substance, which they believe to be very similar to bradykinin, which is liberated on contact with a foreign surface—although there is a lag period before activity develops reminiscent of the lag in plasma-thromboplastin generation With such a plurality of vasodilatory mechanisms and agents, one is temporarily left somewhat doubtful of the wisdom of Isaac Newton's axiom *Natura enim simplex est* However, many of these findings are based on test-tube observations under conditions not strictly comparable to those in injured tissues, though they may well illuminate the biological mechanism I believe it is possible to put forward a hypothesis, based on experiments of this type and direct observations on the changes in connective tissue due to localised injury such as has been made by Zweifach (1954), Allison et al (1955), and others, and of course, like any heuristic approach to a problem, it is propounded for destruction rather than acceptance

A HYPOTHETICAL INFLAMMATORY SEQUENCE

The earliest change to be observed in the immediate vicinity of an area of microtrauma is a degranulation of mast cells and a change in the ground substance so that it becomes more fluid, so there has been a local release of histamine, heparin, 5 H T, proteolytic enzymes of the cathepsin type and tissue thromboplastin (Mast cells are extremely easily damaged and the release of these agents could well induce the physical change in the ground substance) Next alterations are observed in the adjacent capillaries—I am not attempting to describe in detail all that can be seen—a thickening of endothelium or a laying down of gelatinous material on the intravascular surface nearest to the injury To this leucocytes become adherent, and they then emerge through the wall in a random manner, consequent on their motility rather than chemotactic influence, there appear to be local defects in the capillary wall, the while there is degranulation of the pericapillary mast cells, with increasing œdema of the ground substance, which becomes more metachromatic We can interpret this as indicating that, either as a direct action of the injury on the endothelial cells or mediated through the substance released from locally damaged mast cells, there has been a cytoplasmic exudate to which platelets become adherent and thereafter rupturing to release coagulation factors and 5 H T which acts as a mediator of histamine release In this gelatinous exudate to which fibrin has now been adsorbed, there is dissociation of plasma proteins with activation of permeability factors which may perhaps act directly on the inter endothelial cement Once a stage such as this is reached it is easy to visualise, as a result of exudation of plasma and leucocytes into the ground substance, a whole series of reactions which can explain, in pharmacological terms, the morphological changes to be observed in the early inflammatory reaction

However, as we pile assumption upon experiment, we should remember Madame de Deffand's reply to Cardinal Polignac when he was trying to impress her with the miracles of St Denis, the first Bishop of Paris, and told her that the saint, after his execution, carried his severed head from the headsman's block in Montmartre to the site of the abbey which bears his name, "and thus," said the pompous prelate, "was a distance of no less than two leagues" "Ah, Monseigneur," replied the Marquise, "I believe in such circumstances it is only the first step that counts" It is the first step that matters in explaining so many pathological processes, and it is usually the most difficult phase to analyse

In regard to inflammation, we must recognise, as Kettle showed so clearly, that each injurious agent will modify the inflammatory reaction perhaps by reason of the physiological activities of the agent itself, as is the case in the stings of plants, venomous beasts, and bacteria, or by direct action on the cells or their metabolic processes

THE REACTIONS TO BACTERIAL INVASION

When we consider the reactions to bacterial invasion, there is once again the necessity of trying to determine what happens in the tissues in relation to the presence of bacteria as against the findings of innumerable in-vitro experiments

Naturally, we think first of phagocytosis, and, though it is still just as certain that the ingestion of micro-organisms by neutrophil leucocytes and macrophages is of prime importance in the initial localisation of an infection, yet it is also quite clear that it is not the straightforward teleological battle that Metchnikoff described in Odessa seventy years ago

We do not know why it is that some organisms which appear tough are readily destroyed, while others, which are delicate, such as brucella, proliferate and give rise to intracellular infections, and others such as the leprosy bacillus enjoy an intracellular parasitism The battery of enzymes present in leucocytes, although able to break down dead organisms, have no effect on living bacteria The one exception is lysozyme, in which neutrophils are very rich, but once again there are few living organisms which lysozyme can attack, although it has a wide bacteriostatic range and the high lysozyme content of inflammatory exudates may well be of importance Recently Hirsch (1956) has described a protein, phagocytin, which has bactericidal properties for gram negative organisms and is present in high concentrations in neutrophils but apparently is only to be found in the rabbit A number of other antibacterial substances, basic peptides for instance, have been obtained from necrotic tissues, but there is little evidence as yet that they play any part in natural defence

It is quite probable that the inflammatory milieu is of greater importance in the localisation and destruction of bacteria than the activity of antimicrobic substances of cellular origin

The physical characters of inflamed connective tissue, with its collagenous membranes and gelatinous ground substance and fibrin network, would tend to localise micro organisms and facilitate surface phagocytosis Then there is the marked acidity, both of the phagocytes themselves and of the extracellular environment, consequent on the release of lactic acid due to the glycolytic fermentation Pathogenic organisms are very sensitive to acidity and more particularly to the type of anions present, lactic acid is much more toxic than keto acids, and this may be one of the factors that influences the course of infections in diabetes and during cortisone therapy, for it has been shown that under these conditions leucocytes form less lactic acid

Interest in the non-specific humoral factors has recently been revived by the work of Pillemer (1955) on properdin and the related work by Rowley (1956) on bacterial lipopolysaccharide

Pillemer and his co-workers showed that there is present in the normal serum of man, and of many other species, a bactericidal system effective over a large range of micro-organisms and viruses which does not require specific immunisation for its activity Its components are properdin, a globulin of high molecular weight, the four parts of complement, and magnesium ions. Lipopolysaccharide fractions of bacterial cell walls enhance the properdin levels and it has been suggested that a specific configuration of the polysaccharide of the cell walls acts as a specific receptor site for the properdin system, thus enabling the destruction of bacteria to proceed It is possible that the infection-promoting activity of epithelial mucins and certain complex sugars, such as highly polymerised dextrans and levans, may be due to their ability to combine with properdin and neutralise it, and that in certain micro organisms the cell wall may be covered with antigenic envelopes so that the properdin receptor sites are blocked

Apart from stimulating properdin, bacterial lipopolysaccharides initiate a whole range of physiological reactions in the host—fever, leucocytosis, stimulation of the reticulo-endothelial system and adrenal cortex, Schwartzman activity, and the specific immune response

I shall not attempt to deal with the immunological reactions to micro organisms, as I have tried to restrict myself to the early stages of infection Although antibodies cannot be recognised in the blood-stream for several days after an initial infection, it is important to remember that they may be formed locally in a matter of hours, though in quantities too small for their overflow into the circulation to be detected There is some experimental work in favour of this idea, and if it could be substantiated it would explain a number of anomalous observations with regard to local resistance to bacterial infection

A Detour to Look at Snake Venom

Now I would like to depart from my main theme for a few minutes to discuss the biology of snake venoms, because it is related on the one hand to the initial inflammatory tissue reactions and on the other hand to the effects of micro organism on the tissues, which I shall be considering shortly

Snake venoms are generally regarded as one of the most lethal of biological secretions and are known to contain a whole range of enzymes in high concentration The type of reaction varies from species to species and in the same species according to its physiological state and habitat, but in essentials there are two phases—the local and systemic effects The local effects are characterised by intense pain and swelling at the site of injection which becomes hæmorrhagic and necrotic, while the systemic effects may be paralysis in the case of colubrine venoms, or shock and circulatory failure in the viperine venoms

Analysis of snake venoms has shown a remarkable spectrum of enzyme activity (hyaluronidase, lecithinase, protease, peptidase, phosphatase cholinesterase, and ophio amino acid oxidase) and it is possible to correlate quite closely the changes observed in animals exposed to the venoms with the known action of their constituent enzymes—for example the hyaluronidase, by its action on mucosubstances in the connective tissue, will facilitate the penetration of the venom, the lecithinase will act on capillary endothelium and erythrocytes, the proteinases will produce their effects on blood coagulation, the cholinesterase on nervous transmission, and so forth. Indeed, it is obvious that they form a most effective offensive weapon, but perhaps this is an unduly anthropocentric reflection and it is well to consider that matter from an evolutionary standpoint. Serpents cannot chew or tear their food to pieces, the while lubricating it with digestive enzymes, they swallow the rodents, or other small mammals which are their normal diet, whole, and yet their digestive enzymes must be able to play their part in nutrition. The most primitive snakes have a simple fang structure at the rear of the upper jaw, and the venom producing glands are related to the salivary glands, as their prey is swallowed it is injected with venom. During the course of phylogenetic development, the length of the maxilla decreases and the fangs shift towards the front of the mouth and develop into weapons of attack. Nevertheless, with the exception of hyaluronidase and ophio amino oxidase, all the enzymes found in snake venoms are present in the digestive juices of other animals, and contrariwise it is possible, for example, to detect thromboplastic activity in human saliva. Ophio amino oxidase, which appears to be peculiar to snakes, is not a toxic enzyme but is able to activate the proteases and peptidases of the prey and so facilitates their digestion, it is probably a factor in the rapid necrosis that occurs in snake bites.

I have taken this detour because it emphasises, I believe, the point that our interpretation of the effects of substance produced by living material on their hosts or prey is tacitly teleological, whereas it may be that in the normal environment these substances are but metabolic by-products or play a part in the organism's nutrition.

Micro-organisms in Relation to Disease

Now how should we approach the problem of the mechanism of disease production by micro-organisms? It is only eighteen months ago that there was a symposium on this very subject under the ægis of the Society of Microbiology, and the difficulties, both semantic and experimental, were admirably discussed by Miles (1955b). I wish to evade the problems of definition and see how far we can go in assessing which, if any, definite characters of a micro-organism can be related to the clinical and morphological features of the disease state with which it is associated.

But there are still a number of problems to be faced. There is the circuitous difficulty that, in many disease states, the morphological lesions are not of themselves so characteristic that we can say this can only be an infection due to such and such an organism—although, as Kettle rightly pointed out, the reverse is more often true as far as a group of organisms is concerned.

Then we have the far more serious difficulty that it does not follow that the metabolic character of a micro-organism grown on artificial media are those which it reveals when growing in vivo. This is well recognised, and attempts have been made to overcome it—e.g., the work of Watson and Cromartie (1952) on the streptococcus and anthrax which has been continued by Smith et al. (1955), and Lurie's (1939) studies on tuberculosis. Although the results of this sort of work are often disappointing and confusing, in contrast to the clear-cut findings that may emerge from in-vitro experiments, yet I believe they must be persisted with because they can simulate natural disease, and techniques using the hamster pouch or granuloma pouch of Selye might well prove of value. Even when we think we have all the information—the morphological characters of the lesions, the mode of action of the bacterial factors which are associated with virulence—we may still be left qu uncertain as to how to integrate the information and display the stages by which these virulent factors induce not only the local lesion of the disease but also those systemic features which are often the real characteristics of an infection. Nor will immunology always help us to determine which are the harmful factors: the strain of diphtheria which is most effective in producing antitoxin has never been known to produce the disease, and the strain of *Clostridium welchii* used for the same purpose came not from a case of gas gangrene but from an old hat!

With all these difficulties before us, is it worth while for a morbid histologist to try to offer any observations about the pathogenesis of infection? I hope it is. Even if I fail to convince my bacteriological colleagues, my jejune speculations may perhaps stimulate them to look into these problems further.

THE STAPHYLOCOCCUS

In man the staphylococcus manifests itself in three principal forms: (1) circumscribed purulent lesions which may be localised or associated with a bacteræmia transient or persistent, (2) widespread membranous lesions, such as may occur in the respiratory passages or the intestinal tract, and (3) the severe shock-like syndrome which was seen so dramatically in the Bundaberg disaster, when a number of children died after being injected with a diphtheria toxin antitoxin contaminated by a staphylococcus. The staphylococcus is known to have a whole range of toxins—hæmolysins, leucocidins, fibrinolysin, hyaluronidase, and coagulase—but there is little possibility, as yet, of discovering the relation between these factors (some of which are enzymes) and staphylococcal disease.

Menkin (1935) suggested that localisation of staphylococcal infection occurs very rapidly because of the occlusion of the adjacent lymphatics by fibrin thrombi, but Miles (1955a) was unable to detect any lymphatic blockade in the first few hours of infection, and Young (1954), using the hamster cheek pouch, came to the same conclusion.

Young's observations were of some interest, in the first two hours the changes were of the classical reaction-to-injury type and were limited to the site where the organisms were injected. After that the vascular connective tissue changes became generalised throughout the pouch, and from five to twenty-four hours staphylococci could be cultured from anywhere in the pouch, but by forty-eight hours, an abscess had developed which was always at the initial point of infection, and by this time the rest of the pouch had become sterile.

One of the many problems of the staphylococcus is the undoubted relationship of pathogenicity with coagulase production. Until recently there was little evidence that the coagulase property was itself harmful, but Smith and Johnstone (1956) have just reported that in large doses it is lethal to rabbits with widespread intravascular thrombi, and Boake (1956) has claimed that immunisation with coagulase gives some degree of protection. Smith and Dubos (1956) showed that in mice the reaction to virulent and non-virulent staphylococci, injected intravenously, is similar to that observed with many other organisms, there is initial destruction of both forms apparently equally, and then the few coagulase-positive organisms which have survived inside phagocytes begin to multiply and produce local abscesses.

This ability to survive and multiply after the initial destruction is very characteristic of virulent organisms and so far as I know there is no satisfactory explanation for it. The suggestion has been made that virulent organisms form proteolytic enzymes which destroy part of their antigenic structure and so reduce their immunising activity, Lord Stamp (1953) has shown that such a phenomenon can occur in vitro and certain protozoa have an infinite capacity for altering their antigenic pattern

The staphylococcal filtrate—presumably the α hæmolysin—has a most powerful vasoconstrictor effect and there is no doubt that its dermonecrotic property is consequent on this Thal and Egner (1956) showed that when the filtrate was given intravenously, in addition to the renal vascular changes which de Navasquez (1938) studied it caused omental sequestration and a drop in portal venous pressure which is in accord with the shock syndrome

THE STREPTOCOCCUS

Our ignorance of the mechanism of staphylococcal pathogenicity is all too apparent, and when we turn to the streptococcus our plight is even worse Again there is a galaxy of toxins—erythrogenic toxin, streptolysin, leucocidin, fibrinolysin, hyaluronidase, protease, ribonuclease, and desoxyribonuclease Most of them have been separated on immunological grounds, but this gives us little guidance to the morphogenesis of streptococcal infections Naturally, the erythrogenic toxin is associated with the rash of scarlet fever, the hyaluronidase will assist penetration of ground substance by hydrolysing mucosubstances, and there is evidence that hyaluronidase production is often more active in vivo than in vitro Perhaps the fibrinolysin plays a part in lysing or preventing the formation of fibrin coagula, thus explaining the spreading character of a streptococcal cellulitis, while the ribonuclease will depolymerise viscid exudates rich in nucleic acids But all this provides us with a not very illuminating picture of streptococcal activity However, there are one or two additional clues with regard to two conditions which are undoubtedly associated with streptococcal infections—nephritis and rheumatic heart disease

Rammelkamp (1956) has shown that there is an association between the occurrence of acute glomerulonephritis and nasopharyngeal infection with strains of streptococci belonging principally to groups 12 and 4 This is in keeping with a number of other observations on the epidemiology of streptococcus induced disease, and naturally the idea of specificity is attractive, but there have been a lot of disease specific streptococci in the past For example, Kettle's second publication (1912) written conjointly with two senior clinicians, was on the Histology of Experimental Rheumatism, and its authors came to the conclusion that the cardiac lesions induced in experimental animals by the injection of the "Diplococcus rheumaticus" of Poynton and Paine were identical with those of rheumatic fever in man Fifteen years later Kettle said "At one time I was prepared to accept the rheumacoccus, partly, perhaps, because I was rather biased in its favour, but chiefly, because I was not conversant with the histological lesions of rheumatism" Kettle never forgot that paper, there was no doubt that he had been hurried into publication by the impatience of his senior collaborators—a misfortune that is liable to happen to most of us—and that the atmosphere of the Cancer Hospital laboratory where he was working under Alexander Paine was conditioned in favour of the specificity of the rheumacoccus But the moral he drew from it all was an oft repeated dictum "Never publish a paper till you're reasonably certain that you won't regret it five years later"

Since 1912 there have been innumerable attempts, by many and various methods, to reproduce the morphological lesions of rheumatic fever in animals Although there has sometimes been similarity, there has never been identity, and that is not altogether surprising, for no disease in one species is identical with that in another and this is especially true of chronic diseases

One of the problems with regard to rheumatic fever in man is that only a small proportion (about 3%) of people with streptococcal infections develop rheumatic fever, but one attack increases susceptibility to reinfection, and antibiotic therapy of throat infections reduces the likelihood of the heart being attacked again Various long-term experiments, such as those of Murphy and Swift (1949) and Glaser and his colleagues (1956), in which repeated streptococcal infections have been induced in animals, have resulted in a small proportion developing myocardial lesions quite closely resembling the Aschoff nodule, furthermore, focal myocardial lesions can be induced by intravenous streptococcal proteolytic enzymes But the most exciting possible link is the work of Bernheimer and his colleagues (1945, 1950, 1956) with streptolysin O

About ten years ago it was shown that if you exposed an isolated frog's heart to streptolysin, nothing happened, but if the heart was washed and then treated with a second dose of hæmolysin it immediately went into systolic contraction The first dose liberates an inhibitor (probably cholesterol) but this is removed by washing and the heart is then able to react to the second dose

When this procedure was applied to mammalian hearts, the coronary arteries went into spasm, and then there was permanent and irreversible loss of myocardial contraction It was not necessary to apply two doses to release the inhibitor as was the case in the frog's hearts, but the reaction could be inhibited by cholesterol and the streptolysin had to be activated by cysteine

Going from a heart infusion preparation to a suspension of mitochondria in a Warburg flask, Bernheimer and his colleagues were able to show that preparations of streptolysin O interfered with the oxidative metabolism of the mitochondria The selective nature of the inhibition, suggested that there was interference with the action of diphosphopyridine nucleotide or co-enzyme I, and that the bacterial extract contained an enzyme which broke down the oxidised diphosphopyridine nucleotide

Here we have clear evidence of a biochemical lesion, in Peters's sense of the word, but the question remains as to how, if at all, it is related to rheumatic fever, and we must not forget that Miles (1955b) has warned us to beware of the fallacy of the appropriate substrate Nevertheless, this does offer a clue we have evidence that a streptococcal filtrate can interfere with myocardial metabolism, and, if that is so, then we have an explanation for the localisation of lesions in the myocardium in rheumatic fever without invoking immunological hyperactivity, which is probably all important for the generalised connective tissue manifestations It might be objected that these muscular lesions are irrelevant as the primary lesions in rheumatic carditis are in the interstitial tissue, but this is open to argument Some, like Murphy (1952), believe that damaged muscle fibres are the primary factor in the histogenesis of the Aschoff nodule, and even the most extreme supporters of connective-tissue alterations, such as Wagner and Tedeschi (1955) agree that there is muscle damage and that myogenic giant cells (distinct from the Aschoff giant cell) may be present in the Aschoff nodule

DIPHTHERIA

Having dealt at length with two groups of organisms in which our knowledge of the pathogenic mechanism is poor, are there any in which it is not so poor? Yes, I think there are a few Pappenheimer (1955) has made a detailed study of diphtheria toxin, which is a protein with a molecular weight of about 72,000, and has found suggestive evidence that it acts by blocking the synthesis of cytochrome C It has been known for some time that an excess of iron in the culture medium interferes with the production of diphtheria toxin, and that when toxin is produced a porphyrin pigment is also released into the medium Furthermore, it has been shown that, when excess iron is added, every four atoms of the metal inhibit the production of four molecules of porphyrin and one of toxin, if still more iron is added, instead of toxin, a respiratory pigment resembling cytochrome C appears Now cytochrome C contains four hæm radicals per moiety, so diphtheria toxin could be the protein moiety of diphtherial cytochrome C, and in a susceptible animal might block the synthesis of cytochrome C There are several other points which support this hypothesis, but it presupposes that the turnover of cytochrome C within the cell is very rapid, and there seems to be no evidence on this

TETANUS AND BOTULISM

There are a number of other bacterial toxins which, although differing markedly in their pharmacological properties from diphtheria toxin, have certain features in common with it, such as extreme potency and a long latent period before any symptoms develop, which suggests that they act not as enzymes themselves, nor by inhibiting existing enzyme systems, but by interfering with the synthesis of essential cellular constituents

I am thinking, particularly, of tetanus and botulinum toxins, the neurotoxin of Shiga, and some bacterial plant diseases Botulinum toxin is possibly the most toxic substance known 1 mg contains 1,200,000,000 M L D per kg of guineapig, and the toxic dose is believed to be about 5 molecules per nerve cell Payling Wright (1954) and his colleagues have made an intensive study of botulism and tetanus, from which it is fairly clear that, while both are strict neurotoxins, botulinum toxin acts solely upon cholinergic nerve endings of peripheral fibres, whereas tetanus toxin operates upon nerve cells in brain and cord Probably both toxins affect the synthesis and liberation of acetylcholine, possibly by interfering with choline metabolism

GAS GANGRENE

I could discuss many other infections—anthrax, cholera and its mucinase, the endotoxins of the gram-negative organisms, and the obscure problems of tuberculosis, but I would like to select as my last example gas gangrene—not only for its own interest but because it played a significant part in the development of Kettle's research interests In 1916 at the laboratory of the 3rd London General Hospital he studied gas gangrene, which had only just been recognised as an entity, and he later provided an admirable account of its histopathology for the Medical Research Council's report on anaerobic infections During this work he became intrigued with the phenomenon of defence rupture, as Gye and Cramer (1919) called it If washed spores of gas gangrene or other anaerobes are introduced into the tissues of an animal, no disease usually develops, but if a small quantity of broth culture is injected, or if washed spores with calcium or silica are introduced, fatal gas gangrene develops in twenty four hours Kettle showed that the phenomenon was not restricted to anaerobes but also occurred with streptococci and diphtheria From these experimental combinations of bacterial and non bacterial inflammatory agents, it was not a long step to the problems of the tubercle bacillus and silica, on which he made his major contribution to knowledge

Sir Paul Fildes (1927), in his studies on tetanus, elucidated the phenomenon of "defence rupture," showing that the factor which determined germination of spores and multiplication of the vegetative bacteria was a drop in the oxidation reduction potential to a critical low level This could arise as a result of ischæmia, anoxia due to proliferation of contaminating bacteria, or autolysis of dead tissue

Now in gas gangrene we have a very striking example of a disease with both local and systemic manifestations Sometimes the local lesions may appear quite trivial compared to the profound collapse with circulatory failure from which the patient dies If we examine the local site the appearances range from muscle, which is pale and does not bleed or react to stimuli, to a pultaceous pinkish mass and finally a greenish black diffluent mass associated with a large amount of exudate and gas, while there may be necrosis of the skin with bleb formation The other organs seldom show any very striking changes, apart from some fat embolism in the lungs and perhaps acute tubular necrosis in the kidneys

Microscopic examination of the muscle shows a wide separation of the fibres by an œdema of the endomysial connective tissue with a striking lack of fibrin or neutrophil leucocytes in the exudate, there is disruption of the sarcolemma and disappearance of sarcolemmal nuclei These changes are agreed by all workers, but beyond this there is disagreement both as to the degree of destruction of myofibrils and the disappearance or preservation of reticulin and collagen fibres As is usual when there is a dispute in matters of observation, it is impossible to say who is right, because the techniques of different workers vary and clearly it is unfair to compare too closely the tissue changes in naturally occurring gas gangrene in man with the alterations observed by exposing animal muscle to clostridial filtrates in vitro (Robb Smith 1945, Aikat and Dible 1956)

As there is disagreement on the nature of the local lesions, so there may also be disagreement on the mechanism by which the changes are induced, and when one considers that *Clostridium welchii* filtrate contains α-toxin, the lecithinase, θ-toxin, a possible leucocidin ϰ toxin, the collagenase, and hyaluronidase as its known components, and that the proportions of these vary from strain to strain, there is considerable opportunity for differing viewpoints However, there is no disagreement that the α-toxin or lecithinase is the principal lethal factor, with its action in the first instance on the cell membrane, whether of capillary endothelium or sarcolemma Consequent on this there will be an exudate of fluid into the ground substance already modified by the action of the hyaluronidase and the fibrinolysin postulated by Reed and his co workers (1943) Macfarlane and Dupton (1954) have shown that the lecithinase can break down the phospholipids of mitochondria with inactivation of succinoxidase, a very important link in the oxidative mechanism of the cell It is clear that a widespread intercellular metabolic disturbance of this type could well be associated with the peripheral vascular failure that is so characteristic of the disease, although Ganley et al (1955) have postulated a "circulation factor" distinct from any of the known toxins But I believe we must also pay attention to the effect of lecithinase on cytoplasmic permeability and the consequent disturbance in body-fluid distribution So far I have not mentioned the collagenase first identified by R G Macfarlane and Maclennan (1949), Evans (1947) has shown that it is not a major lethal factor, but I still feel that there is good evidence that it plays a part in the local spread of clostridial infection

Silicosis

It would have been agreeable if I could have concluded this lecture by discussing the proximate mechanisms in silicosis, but in reality we cannot add much to what Kettle and Gye (1922) said thirty-four years ago in their first paper on the subject "Just as, in a physiological sense, no material is of use for energy purposes unless it is soluble, so pathologically, with certain obvious mechanical exceptions, it is only soluble substances which can exert a substantial or a continuous effect on the tissues"

King et al (1956) have reviewed the solubility theory very carefully, and feel that, in spite of certain inconsistencies, it is the most probable, but this still [illegible] to be explained Holt and Osborne's (1953) suggestion that polymerised silicic acid might function in the connective tissue as a macromolecule analogous to a mucopoly saccharide, and so induce collagen formation, is attractive, but I feel does not altogether conform with recent work on fibrillogenesis On the other hand, MacLeod and Roe's (1956) observation that silicate in low concentration was lethal to pneumococci and streptococci and changed their reaction to the gram stain does perhaps contain a germinal idea This phenomenon could be inhibited by lecithin, choline, and substituted ammonia compounds, but not by cholesterol This might indicate a disturbance of the cytoplasmic membrane, and if such a disturbance could be substantiated one might begin to determine the biochemical lesion in silicosis

* * *

I tried to forewarn you that I would present the way in which I believe morphological pathology is exploring disease mechanisms, and the successes, limited though they may be, that have been obtained in the field of inflammation and infection I can only hope that for some of you it has raised questions to be resolved and assumptions to be tested, and is a reminder that there is still much work to be done in the way that Kettle did it

the condition, and gross electrocardiographic abnormalities were present either at rest or after exercise. Two of these patients were in hospital at the time of the investigation.

The controls were healthy volunteers selected to correspond to the patients in age and sex. None had a history in any way suggestive of cardiac disease, but they were not otherwise investigated.

Dietary histories were taken by the same dietitian from all the people taking part in this investigation. From these histories the daily intake of calories and fat (animal and vegetable) were roughly estimated. The mean values for the coronary and control groups are shown in table II. The mean value for the intake of animal fat appears to be somewhat lower in the patients with coronary artery disease compared with the controls, but the difference is by no means significant (P=0.3). The other values are very similar in the two groups.

Methods

Collection of Blood

50 ml. of blood was drawn from the antecubital vein into acid citrate dextrose anticoagulant at least 15 hours after the last fat containing meal. The blood was kept at +4°C until required for analysis, which was never delayed longer than 24 hours.

Separation of Lipid Fractions

The blood was centrifuged to separate the red cells, which were then washed once with 0.16 *M* NaCl solution to remove trapped plasma. 20 ml. portions of both plasma and packed red cells were then added with vigorous stirring to two separate 400 ml. portions of 2 : 1 ethanol ether. After standing at room temperature for 15 hours the precipitated protein was removed by filtration, and the lipid solutions were evaporated to dryness in vacuo on a water-bath at +40°C. Before evaporation 1.0 ml. of 0.01 *M* uranyl sulphate solution was added to the plasma lipid solution to facilitate the separation of the phospholipids from the other lipid components. After evaporation the dry residue of the plasma lipids was immediately extracted with two successive 15 ml. portions of acetone.

The lipids in this fraction are called "the acetone soluble lipids of the plasma" and include principally glycerides and cholesterol esters. The lipids of the residue remaining after the acetone extraction are called "the phospholipids of the plasma". After the removal of solvent both fractions were hydrolysed by the addition of 5.0 ml. of 40% KOH and 25 ml. of 50% ethanol and heating to 60°C for 4 hours in a water bath. Unsaponified material was removed by extraction with light petroleum (40–60°C boiling range), and the fatty acids were liberated from the hydrolysate by the addition of 10 ml. of 10 *N* H_2SO_4.

TABLE II—MEAN INTAKE OF FOOD BY PATIENTS AND CONTROLS AS ASSESSED BY DIETARY HISTORIES

Group	Total calories daily	Intake of fat (g. daily)		
		Animal fat	Vegetable fat	Total
Patients with coronary disease	2372	88	23	111
Controls	2489	105	23	128

The fatty acids were isolated by three successive extractions with ether. The ether solution was then dried over anhydrous Na_2SO_4 and evaporated to dryness. Immediately after the evaporation of the ether the acids were esterified by dissolving in 10 ml. of anhydrous methanol containing HCl and heated under reflux for 2 hours. The methanol was then removed by evaporation in vacuo, and light petroleum was added, followed by a little water. The aqueous layer was twice extracted with light petroleum, and the extracts were combined, washed with dilute $NaHCO_3$ solution to remove free acid, and finally dried over anhydrous Na_2SO_4. The fatty acid-methyl ester solutions were stored at +2°C.

Fatty acids and their esters are stable when stored in dilute solution at this temperature; losses seem to take place only when they are dry and in contact with air. Before the application of the sample to the gas column the solvent was removed by evaporation on the water bath. At no time were the dried samples exposed to atmospheric oxidation for more than a few minutes.

Gas-liquid Chromatography

The samples were applied with a micro pipette to the gas-liquid chromatograph described by James and Martin (1952) for the separation of the methyl esters of long chain fatty acids. The columns used were 4 ft. long, with a stationary phase of 'Apiezon M' vacuum stopcock grease at a temperature of 197°C. The mobile phase was nitrogen, and the detector was the gas-density meter (*Martin and James 1956*).

TABLE III—FATTY ACID ABUNDANCE OF THE LIPIDS OF THE RED BLOOD CELL

Acid	Mean of 9 patients	Mean of 6 controls	(P)*
Myristic	0.85%	0.87%	0.9
Palmitic	23.0%	22.4%	0.9
Stearic	16.6%	14.7%	0.75
Palmitoleic	1.2%	1.1%	0.9
Oleic	21.3%	19.8%	0.2
Linoleic	11.8%	12.1%	0.9
Arachidonic	14.1%	13.3%	0.5

*(P) indicates the probability that the observed difference between the two means is due to chance.

The fatty acids were measured quantitatively by the triangulation technique described by James and Wheatley (1956). As a test of reproducibility three samples of the fatty-acid methyl esters from the same batch of red cells were prepared by the complete procedure just described. The three chromatograms matched one another.

Cholesterol Estimations

The total cholesterol content of the plasma was estimated by the method described by Bloor (1916). Briefly this was as follows. 1 volume of plasma was added to 25 volumes of 2 : 1 ethanol ether solution, and after being left for 30 minutes the solution was filtered and evaporated to dryness; the dry residue was extracted with three successive portions of boiling chloroform; and the cholesterol was estimated by light absorption with the use of the green colour produced on adding acetic anhydride and sulphuric acid.

Glycerol Estimations

The glyceride glycerol content of the acetone soluble fraction of the plasma lipids was estimated by the method described by Harvey and Higby (1951). In this method glycerol is estimated by light absorption, using the red colour produced by the reaction between glycerol and catechol in sulphuric acid. Glycerol estimations were made on the aqueous solution remaining after the hydrolysis and lipid extraction of the acetone soluble fraction of the plasma lipids.

Identification of Fatty Acids

The time of emergence of a homologous series of saturated fatty acids from the chromatograph column is precisely determined by their chain length (James and Martin 1956), and chemical identification was not considered necessary. The unsaturated acids were isolated and identified by chemical degradation. A preliminary account of the nature of the fatty acids present in plasma lipoprotein, neutral fat, and red blood cells has been given by James and Lovelock (1957).

TABLE IV—THE FATTY-ACID ABUNDANCE OF THE PLASMA PHOSPHOLIPIDS

Acid	12 patients	12 controls	(P)
Myristic	1·1%	1·1%	0·9
Palmitic	25·5%	26·7%	0·9
Stearic	13·4%	13·3%	0·9
Palmitoleic	1·94%	2·03%	0·9
Oleic	20·7%	20·8%	0·9
Linoleic	19·6%	18·8%	0·9
Arachidonic	9·6%	9·7%	0·9

Results

Red blood-cells.—At the beginning of the investigation the fatty-acid composition of red cells from different human sources was determined. They were remarkably constant from person to person regardless of age, sex, and state of health. A complete comparison of the fatty acids of the red cells of all of the patients with coronary-artery disease and their matching controls was not therefore made. Table III shows the fatty-acid composition of the red cells of nine patients with coronary-artery disease and that of six normal persons not of the same age and sex. The means were compared according to the '*t*' test, and the probability that the differences between the means were due to chance is shown in the table. It can be seen that the two groups are not significantly different.

Phospholipids of plasma.—Table IV shows the composition in terms of the main components of the fatty acids of the phospholipid fraction of the twelve patients with coronary-artery disease and of their matching controls. The probabilities that the differences between the mean compositions of the acids of the two groups were due to chance are also shown and again indicate that there are no significant differences between the two classes.

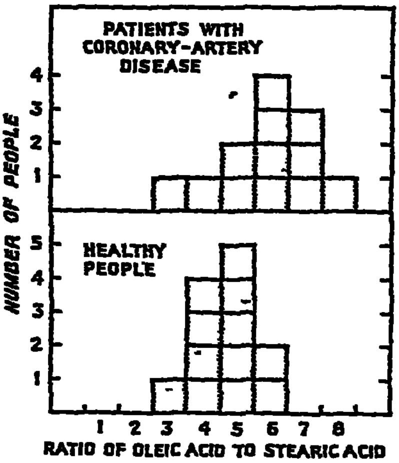
Acetone soluble fraction of plasma.—Table V shows the fatty-acid composition of the acetone soluble fraction of the plasma of the twelve patients and of their matching controls. The total cholesterol content and the glyceride-glycerol of the plasma in the two groups are also shown. The probabilities that the differences between the abundances of the components in this fraction were due to chance are shown, and, unlike the fatty acids of the red cells and the phospholipids, seem to be verging on significant differences for some of the fatty acids. Values for glyceride glycerol and for total cholesterol were not significantly different in the two groups.

Discussion

We know of only one other comparison of the fatty-acid composition of normal blood and blood from atheromatous patients—namely, that of Hammond and Lundberg (1955). Their work differed from ours in important respects: their controls and atheromatous patients were not matched for age and sex, blood was taken 3–4 hours after a fatty meal, and the analyses were done on whole plasma. In addition, the analysis was spectrophotometric, which means that groups of fatty acids of equal degrees of unsaturation were measured rather than single components as in our technique. Hammond and Lundberg found an apparent small decrease in the proportions of di- and tetra- unsaturated acids in the atherosclerotic patients; but, when these were corrected for the level of total fatty acids, there was no difference in the amount present per 100 ml. of plasma in the two groups. The main components of the di- and tetra- unsaturated acids are linoleic and arachidonic acids respectively. In our study there was no difference in the proportion of these acids found in controls and patients either in the red-cell, in the plasma-phospholipid, or in the plasma acetone-soluble fractions. Linoleic and arachidonic acids are often described as "essential fatty acids," and it has been suggested that deficiency of essential fatty acids may be a factor in the causation of atherosclerosis (Sinclair 1956). Our results do not support this idea.

TABLE V—FATTY ACIDS, CHOLESTEROL, AND GLYCERIDE GLYCEROL OF THE ACETONE SOLUBLE FRACTION OF THE PLASMA LIPIDS

Lipid component	Composition in 12 patients	Composition in 12 controls	(P)
Mean abundance of fatty acids (%)			
Myristic	3·5%	4·7%	0·1
Palmitic	23·9%	24·1%	0·9
Stearic	6·9%	7·7%	0·3
Palmitoleic	5·3%	4·6%	0·1
Oleic	38·1%	34·7%	0·06
Linoleic	12·1%	12·4%	0·9
Arachidonic	2·7%	2·6%	0·9
Total mono unsaturated acids C_{14}, C_{16}, and C_{18}	45·9%	41·6%	0·05
Other lipid components (mg. per 100 ml. of plasma)			
Cholesterol	197·0	159·7	0·5
Glyceride glycerol	4·4	4·0	0·6
Ratio of oleic acid to stearic acid	5·8	4·6	0·02



Frequency distribution of values of the oleic-acid stearic-acid ratio of the acetone-soluble fraction of the plasma lipids.

The general fatty-acid pattern in both the red-cell and plasma-phospholipid fractions is remarkably constant in spite of differences in age, sex, diet, and state of health. In the acetone-soluble fraction of the plasma most of the fatty acids are present in similar proportions in the controls and in the patients. The preliminary investigation of the fatty acids of the acetone soluble fraction of the plasma of young persons, particularly young women, showed that mono-unsaturated acids are significantly less abundant in this group than in our patients with coronary-artery disease. This observation led us to compare the proportions of the mono unsaturated C_{14}, C_{16}, and C_{18} acids in the patients and in their matching controls. The mean proportion of these acids taken together was higher in the patients than in the controls, but only at a low level of significance ($P = 0·05$). The main component of this group of mono-unsaturated acids (oleic acid) is not by itself significantly different in proportion in the two groups at the 5% level. Oleic acid may, however, reasonably be related to its corresponding saturated acid, stearic, with which it is believed to be interconvertible in the body. When the ratio of oleic to stearic acid was compared in the two groups it was found that the mean value in the patients was higher than in the controls ($P = 0·02$). A histogram of the individual values of the ratio of oleic to stearic acid for the two groups is shown in the accompanying figure.

These small divergencies in the C_{14}, C_{16}, and C_{18} mono unsaturated acids of the acetone soluble fraction would not be remarkable were it not for the contrast provided by the extreme constancy of most of the other fatty acids, and of those same fatty acids in the red cell and plasma-phospholipid fractions. It may well be that the differences would be more striking if the patients with coronary artery disease could be compared with controls whose coronary arteries were certainly healthy, for the most that can be said of our controls is that they have not yet shown any clinical manifestations pointing to this type of disease The difficulty in demonstrating differences in a small series such as this, where the controls are inevitably not "pure controls," is illustrated by the fact that the mean plasma-cholesterol level and the glyceride glycerol level were not significantly different in the two groups, although we do not question the fact that, in a much larger series, the plasma-cholesterol level has been shown to be higher in patients with coronary-artery disease

The existence of a significant difference in the ratio of oleic acid to stearic acid in the patients with coronary-artery disease suggests that the disease may be a consequence of some fault of metabolism rather than of diet as is usually held It must be emphasised, however, that the acetone soluble fraction of the plasma-lipids in which these differences are observed is a mixture of glycerides and cholesterol esters Until these two lipids can be studied separately it is unlikely that a clear picture of the differences between the patients and their controls will emerge

Summary

Gas liquid chromatography was used to determine the proportions of a range of fatty acids, from C_6 to C_{20}, in the blood of twelve patients with coronary-artery disease and in twelve controls matched for sex and age For the purpose of this analysis the blood was divided into red cell, plasma phospholipid, and plasma acetone-soluble fractions

In the red cell and plasma phospholipid fractions there were no detectable differences between the proportions of any fatty acids in the patients and their controls

In all three fractions the mean proportions of the "essential fatty acids" (linoleic and arachidonic) were about the same in the patients and in the controls Hence these observations do not support the hypothesis that deficiency of these "essential fatty acids" is a factor in the genesis of coronary-artery disease

In the acetone soluble fraction of the plasma (containing cholesterol esters and glycerides) there was some suggestion of an increase in the combined proportions of mono unsaturated C_{14}, C_{16}, and C_{18} acids in the patients compared with the controls The ratio of the most abundant of these acids (oleic) to its corresponding saturated acid (stearic) was higher in the patients with coronary artery disease The implications of this observation cannot be properly assessed without further resolution of the acetone soluble fraction into its two components, cholesterol esters and glycerides

We wish to express our gratitude to Miss J M Ingles for the dietary histories, and to the consulting physicians of University College Hospital for permitting us to investigate their patients One of us (W R T) is in receipt of a grant from the Sir Halley Stewart Trust

HIATUS HERNIA

David Phear
M.A, M D Camb, M R C P
LATELY MEDICAL REGISTRAR, ADDENBROOKE'S HOSPITAL, CAMBRIDGE *

Widely divergent opinions have been published by physicians and surgeons about the correct treatment of hiatus hernia This difference of views depends on the types of cases which they see Surgeons seldom see mild cases and operate on patients who have not improved with medical treatment, whereas physicians find that the average case responds to medical measures and that surgery is seldom required The present review of 87 cases of hiatus hernia and 20 with gastro-œsophageal reflux alone was undertaken primarily to assess the effectiveness of medical treatment

Material

The material consisted of 45 females and 42 males with hiatus hernia, and 11 females and 9 males with gastro œsophageal reflux alone The cases were unselected, being all those on the diagnostic index of Addenbrooke's Hospital, apart from a few patients who had died or who did not reply to the request to attend for review, All the cases had been investigated for dyspepsia, and the diagnoses had been established radiologically during the four years before review in 1954–55 All the patients were interviewed personally, except 5 who supplied information by letter

Findings

RADIOLOGICAL FINDINGS

Hiatus Hernia

Of the 87 patients 76 had sliding herniæ, 9 had large herniæ of combined sliding and para œsophageal type, 1 had a para-œsophageal hernia, and 1 a short œsophagus A similar incidence of the various types was found by Allison (1951) and Sweet (1952) All the combined herniæ and 41 of the sliding herniæ were larger than 2 5×2 5 cm (measured on the films) No correlation was found between size of the hiatus hernia and severity of symptoms, mild symptoms being associated equally with large or small herniæ All the patients with sliding herniæ had associated gastro œsophageal reflux

Gastro-œsophageal Reflux

In the 20 cases of reflux alone it was radiologically slight in 12 and gross in 8 Symptoms were severe in 11 of the 12 cases with slight reflux and in 6 of the 8 with gross reflux There was thus no correspondence between the clinical and radiological degrees of severity

RELATION OF GASTRO ŒSOPHAGEAL REFLUX TO SYMPTOMS OF HIATUS HERNIA

Intermittent and slight gastro œsophageal regurgitation is a normal event It is therefore difficult to assess the significance of gastro œsophageal reflux in the production of symptoms, and there is no agreement about the relative importance, in the production of symptoms, of a hiatus hernia and of the reflux that almost constantly accompanies it (Olson and Harrington 1948, Collis et al 1954)

In the present series there was no significant difference between the symptoms of patients with hiatal herniæ and associated gastro œsophageal reflux and those with reflux alone Œsophagitis and œsophageal spasm are considered to be responsible for the pain in both groups, and the symptoms were relieved by the same treatment (see below), which is designed to mitigate the occurrence and sequels of reflux *For this reason the symptoms of both classes of patients are considered together*

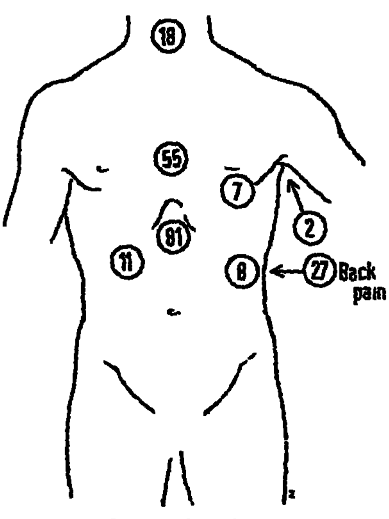
Isolated severe attacks of pain	4	
Regurgitation	3	62
Flatulence		69
Microcytic anæmia	5	18
Hæmatemesis or melæna	4	23
Mild symptoms, pain predominant	14	
Symptom free	2	

SYMPTOMS

Pain

Pain was the predominant symptom in 79 cases and was present in 101 of these 107 patients (table I) It occurred in the situations depicted in the accompanying figure, and many patients had pain at more than one site It will be seen that in 81 patients the pain was central and high in the epigastrium, in 55 substernal, and in 18 referred to the throat Pain in one or both arms occurred in 2 patients with cardiographic abnormalities and in 3 without evidence of coronary disease The pain was typically dull and aching The pain was worse on stooping or on lying down in 56 patients, in 61 it came on after food, within half an hour in 30 It was usually relieved by alkalis with the production of belching

Night pain was a prominent feature in 63 cases and came on an hour or more after retiring in 31 The onset of pain soon after lying down in bed has been regarded as a differential point from the night pain of peptic ulcer, but it is clear that the time-interval after retiring is not constant in the pain of hiatus hernia or reflux Lying on the right side provoked pain in 21 cases, but lying on the left side in only 6 This positional difference is probably due to the fact that, whereas the fundus of the stomach is posterior to the hiatus in the supine and left lateral positions, in the right lateral position the fundus and the hiatus are in the same horizontal plane, thus facilitating reflux (F Pygott, personal communication)



Localisation of pain

Periodicity of pain—Of the 101 patients with pain, 58 experienced exacerbations alternating with weeks or even months of freedom Such periodicity has always been regarded as characteristic of peptic ulceration, but it is evidently shared by hiatus hernia and reflux

Substernal pain suggesting angina pectoris—Isolated attacks of severe pain, such as those described by Bourne (1956) with œsophageal lesions, were initially suspected to be due to myocardial infarction in 4 cases Of these patients 1 showed definite evidence of myocardial infarction, with an almost symptomless hiatus hernia In the remaining 3 patients a hiatus hernia was responsible

Case 1—A woman, aged 44, had an isolated attack of severe retrosternal pain radiating to her back and accentuated by respiration She was dyspnœic and vomited The attack lasted three hours Myocardial infarction was diagnosed, and she was confined to bed for four weeks Subsequent electrocardiogram and radiograph of cervical spine were normal, a hiatus hernia was demonstrated She now notices substernal pain of constricting type spreading to the elbows, occurring inconstantly on exertion, and relieved by rest and by trinitrin She also complains of heartburn and retrosternal pain, worse at night

Case 2—A man, aged 60, in bed in hospital with subacute bacterial endocarditis associated with rheumatic mitral incompetence, had several severe attacks of substernal pain and dyspnœa but no pyrexia or leucocytosis Electrocardiograms were normal, but a hiatus hernia was found Since then he has had retrosternal discomfort which develops on brisk exercise and is relieved by rest

Case 3—A woman, aged 67, had an attack of severe epigastric pain spreading to the left precordium and the back The pain came on while she was sitting, and it stopped suddenly after ten hours There was no angor animi, and she has had no further symptoms An electrocardiogram was normal, but a barium meal showed a hiatus hernia

Angina of effort was present in 9 patients, of whom 7 had hiatal hernia and 2 had gastro-œsophageal reflux alone Milder varieties of pain on exertion, not typical of angina pectoris, were experienced by 11 patients, of whom 9 had hiatal hernia *and 2 gastro-œsophageal* reflux A postural régime for the hiatus hernia produced considerable improvement in 3 patients with angina and in 2 with mild effort pain

Significant abnormalities were present in the electrocardiograms of 6 of the 9 cases with anginal pain, none of the 11 patients with indefinite pains on exertion, and only 4 of the remaining 87 patients showed such abnormalities These findings suggest that hiatus hernia does not, of itself, produce angina on effort, and that when the latter is present it has some cardiac cause Baylis et al (1955) reached a similar conclusion in studies on distension of the lower œsophagus by a balloon in 8 healthy people and in 3 patients with coronary artery disease They found that distension of the lower œsophagus had no effect on the electrocardiogram of the patients with coronary artery disease, and that œsophageal pain was not associated with electrocardiographic change In their opinion the electrocardiogram offered the most reliable means of distinguishing between œsophageal and cardiac pain

Dysphagia

In 21 patients food seemed to stick momentarily behind the lower sternum on swallowing, but there was no true obstruction Pain on swallowing, also localised to the lower œsophagus, was present in 17 patients and was provoked by strong alcohol or hot fluids or foods in 11 Excessive salivation accompanied the dysphagia in 10 patients

COMPLICATIONS OF HIATUS HERNIA

Hæmorrhage and Anæmia

Hæmorrhage and anæmia are common in patients with hiatus hernia (Ritchey and Winsauer 1947, Schwartz and Blumenthal 1949) In the present series 33 patients had either frank hæmorrhage or anæmia Serious hæmatemesis or melæna took place in 15, and in 1 the hæmoglobin was reduced to 3 1 g per 100 ml A microcytic hypochromic anæmia without a history of frank hæmorrhage was found in 10 cases, in 5 of which tests for occult blood in the stools were positive A similar anæmia was also found in 8 patients with histories of frank hæmorrhage in the past

It is of considerable interest and importance that in 8 of the 33 patients with either frank *hæmorrhage or* anæmia the dyspeptic symptoms had been very slight, and in 2 cases presenting with hypochromic anæmia their hiatal hernia were entirely symptomless Large hiatal hernia showed no greater tendency to bleed than small ones

Anæmia and hæmorrhage were only recorded in cases of hiatus hernia and not in those of gastro œsophageal reflux alone. This suggests either that hæmorrhage takes place from the hernia or that œsophagitis is more severe than in cases with reflux alone.

Œsophagitis

In this series œsophagitis was reported radiologically in only 4 cases; subsequent œsophagoscopy in 1 of them revealed a high cardia and reflux of gastric contents but a normal œsophageal mucosa. In 5 other patients examined by the œsophagoscope the mucosa was normal in 3, there was general œsophageal hyperæmia in 1, and an erosion of the gastric mucosa of the hernial pouch in 1. At necropsy on 2 patients who died from unrelated causes the œsophagus was normal in 1 but showed a mucosal erosion in the other.

The demonstrated incidence of œsophagitis in this series is low because œsophagoscopy was only done on a few patients with severe symptoms and not on all patients as a routine, and radiology cannot demonstrate mild grades of œsophagitis.

ASSOCIATED DISEASES

Hiatus hernia is not infrequently found in association with other upper abdominal conditions. It has even been suggested that these promote reflex œsophageal contraction and predispose to hiatus hernia (Gilbert et al. 1946).

TABLE II—ASSOCIATION OF HIATUS HERNIA WITH OTHER ABDOMINAL CONDITIONS

—	Gilbert et al. (1946) 48 cases	Radloff and King (1947) 50 cases	Present 107 cases
Gall stones	14	4	7
Duodenal ulcer	6	3	8
Diverticulosis coli		6	6
Diverticulum of œsophagus	4	1	1
Diverticulum of duodenum		3	5
Totals	24	17	27

Table II shows that 27 of the present 107 patients had associated upper abdominal disease.

In 6 of the 8 cases with associated duodenal ulcer the symptoms were characteristic of duodenal ulcer rather than of hiatus hernia. The diagnosis of a hiatus hernia as source of hæmatemesis in 1 patient was long delayed.

Case 4.—A woman, aged 57, had had since the age of 29 left epigastric pain, worse on stooping or on lying, and coming on two hours after food and in the early hours of the morning. It was not relieved by food or by alkali. She was subject to flatulence, regurgitation, and intermittent dysphagia. Since the age of 16 she had vomited blood at intervals of several years. She underwent partial gastrectomy in 1929 at the age of 31, when a duodenal ulcer was found. She continued to have exacerbations of pain with increasingly severe hæmatemeses, latterly requiring large transfusions. In 1955 a small hiatus hernia with an œsophageal ulcer was demonstrated. Since repair of the hernia hæmatemeses have ceased and pain is much improved.

It is often difficult, too, to decide whether a hiatus hernia or the gall-bladder is responsible for the symptoms.

Case 5.—A woman, aged 53, had had epigastric pain, immediately after food, for eight years, with dysphagia and occasional vomiting. In 1949, at the age of 50, a small hiatus hernia was found, but a postural régime did not control her pain. In 1952 she had a severe attack of right upper abdominal pain with jaundice. Removal of a chronically inflamed gall bladder led to great improvement.

Case 6.—A woman, aged 72, had had for ten years pain in the epigastrium radiating to the back, worse on stooping and on lying, and coming on soon after food. She had dysphagia, regurgitation, and flatulence. Three years ago a chronically inflamed gall bladder containing stones was removed, but symptoms were unaffected. A hiatus hernia was then found, and with conservative treatment symptoms over the past years have been slight.

Case 7.—A woman, aged 59, had had epigastric pain, vomiting, and dysphagia for twenty years. Her pain was worse on lying flat and soon after food and was relieved by alkali. A normal gall bladder had been removed fifteen years before without improvement. Postural treatment for her hiatus hernia has been successful.

Treatment

The aims of treatment are the same for hiatus hernia with associated reflux as for gastro œsophageal reflux alone. They are relief or prevention of reflux œsophagitis which is believed to cause pain either as heartburn or as œsophageal spasm.

(1) Postural measures are adopted to lessen the chances of reflux. Meals are taken by the patient sitting bolt upright or even standing at first; bending forward and sitting in a crouched position are avoided, and at night four pillows are used with 4-inch blocks under the legs at the head of the bed.

(2) Causes of raised intra abdominal pressure are eliminated as far as possible. Weight reduction may be most valuable, the corsets and the bowels are kept loose, and chronic cough is treated.

(3) The acidity of the gastric juice in the lower end of the œsophagus is reduced. Persistent pain and vomiting are usually rapidly relieved by continuous mild drip with the distal end of the Ryle's tube in the upper œsophagus. After a few days the drip may be removed by day, but it should be continued by night as long as any night pain or heartburn persists. When symptoms are not severe, small frequent meals are advised, and aerated drinks, strong alcohol, and excessive smoking are forbidden. After meals magnesium trisilicate powder should be taken, preceded by a few ounces of water drunk by the patient standing up to flush through the œsophagus. A further dose should be taken at bedtime. If pain persists despite these measures, belladonna or propantheline ('Probanthine') may be helpful.

RESULTS OF TREATMENT

Medical

Of the present 107 cases 83 were treated by the full régime outlined above and were followed up after an average period of 14·7 months ($\sigma = 14{\cdot}8$). In the remaining 24 cases postural measures were not needed, either because symptoms were very mild and transient or because anæmia—rapidly corrected by iron—was the presenting feature.

In 58 (70%) of the patients treated the symptoms were well controlled; only 6 of this group were entirely free from symptoms, but the rest had only mild and intermittent dyspepsia. 12 (14%) others experienced much improvement but still found symptoms troublesome. In 13 (16%) there was no improvement, but in 8 such factors as melancholia, uncontrolled obesity, œsophageal stricture, and urethral stricture obviously contributed largely to failure of treatment.

Surgical

Surgical treatment of hiatus hernia is often contraindicated by poor general condition or by advanced age, and postoperative recurrence-rates may be as high as 30% (Sellors 1955). Surgery, however, should be considered when severe pain persists in spite of thorough medical treatment, when *hæmorrhage* is repeated, or when the hernia undergoes rupture, strangulation, or torsion. Strictures are usually amenable to dilatation (Halonen et al. 1952, McGlone and Sawyer 1953). Only 4 patients in this series were subjected to surgery: 2 are symptom free, but 1 of these still has a demonstrable hiatus hernia of moderate size; 1 patient, who survived operation, died shortly afterwards of myocardial infarction; and 1 died from mediastinitis consequent on preoperative œsophagoscopy.

Summary

87 cases of hiatus hernia and 20 of gastro œsophageal reflux are surveyed.

Medical treatment produced good results in 70% of cases, and considerable relief in a further 14%.

Surgery is seldom necessary and often impossible owing to the advanced age of many patients with hiatus hernia

I am very grateful to Dr L C Martin and Dr F Avery Jones for help and advice

INTERMITTENT METHYLTESTOSTERONE THERAPY IN MALE SUBFERTILITY

CLARE HARVEY
B Sc Lond, A R C S

MARGARET HADLEY JACKSON
M B Lond, D Obst

From the Infertility Clinic, Exeter and Mid Devon Group of Hospitals, and the Department of Zoology, University of Exeter

FOR some years it has been the practice at this clinic to treat the husband of a subfertile marriage with methyltestosterone if the quality of his semen is such that he can be regarded as partially or mainly responsible for the failure of his wife to conceive

To avoid the depressive effects of continuous treatment with androgens the methyltestosterone is given intermittently The routine is for the husband to take 10 mg of methyltestosterone daily from the sixth to the sixteenth days of his wife's menstrual cycle, the tablets being dissolved sub lingua If no conception takes place after four to twelve cycles of such treatment, the tablets are discontinued either altogether or for several months, the course then being repeated, sometimes in a higher dosage

In the cases reviewed here, all the couples made their first visit to the clinic between July 1, 1949, and June 30, 1954 Accurate information is available for at least a year, and usually for two years or longer, after the date of the first attendance at the clinic Only cases where at least two specimens of semen were examined before the husband started taking methyltestosterone have been considered The quality of the semen was assessed by the methods described by Harvey and Jackson (1945) and classified according to the mean fertility indices of the two or more ejaculates examined (Harvey 1953) The success of the treatment was measured by comparing the number of pregnancies in each fertility index class with the corresponding pregnancy rate for a larger series of cases investigated in the five years before 1949 The husbands in the control series received no methyltestosterone, but vitamin E was given to nearly all those whose semen had a fertility index below 30 This treatment had no detectable effect on their fertility (Jackson 1948)

Results

Conceptions

Reliable follow up information is available for 148 couples in which the husband was given methyltestosterone 55 of the wives became pregnant within two years of the start of the husband's treatment Half the pregnancies occurred during the first six months' treatment, the remainder being distributed fairly evenly over the following eighteen months Pregnancies are not recorded in this report if they occurred more than twenty-three months after the start of the treatment, because the conception-rate in the controls was based on a two-year period

TABLE I—INCIDENCE OF PREGNANCY IN TREATED AND CONTROL SERIES

Series	Fertility index range of husband			
	Under 30		30–49 (somewhat below average fertility)	50 or more (average to good fertility)
	Less than 10 (very subfertile)	10–29 (definitely subfertile)		
Husband receiving no methyltestosterone				
No of cases	51	90	112	286
No of wives who became pregnant	4 (8%)	20 (22%)	49 (44%)	129 (45%)
Husband receiving methyltestosterone				
No of cases	39	54	33	22
No of wives who became pregnant	16 (41%)	19 (35%)	9 (27%)	11 (50%)
No of pregnant wives expected from untreated series	3	12	14 4	9 9

The fertility indices of the semen covered a range from less than 1 to over 100, but no azoospermic donors were included Where the mean fertility index of the husband's semen is over 50, the chance of conception depends almost entirely on the wife's fertility, and treatment was given to husbands in this group only because of factors other than the quality of the semen, such as partial impotence and lack of libido Where the mean fertility index lies between 30 and 50, though the husband's slightly lowered fertility may somewhat reduce the chances of success of a subfertile wife, the male factor is seldom the principal cause of her failure to conceive It is only when the fertility index of the husband's semen falls below 30 that his fertility level becomes the critical factor in determining conception

Table I compares the number of wives who became pregnant in the two series, the couples being grouped according to the fertility index of the husband's semen

It is apparent from these figures that, whereas in the groups where the husband's semen was of fair or good quality the number of pregnancies did not differ significantly from that expected on the basis of the controls, the number of wives who became pregnant in the groups where the husband's semen may be regarded as the critical factor was more than twice the calculated expectation For the wives of the men with a fertility index under 30 the difference between the pregnancy-rates in the two series is statistically highly significant, and there seems little doubt that in these cases methyl-

TABLE II—COMPARISON OF PREVIOUS INFERTILITY OF TREATED SERIES AND CONTROLS

Series	No of years barren				
	2 or less	Over 2 to 5	Over 5 to 10	More than 10	Total
Husband receiving no methyltestosterone					
No of patients	26 (18%)	47 (33%)	58 (41%)	10 (7%)	141
No of wives who became pregnant	6	12	6	0	24
% successful	23	26	10	0	17
Husband receiving methyltestosterone					
No of patients	16 (17%)	39 (42%)	29 (31%)	9 (10%)	93
No of wives who became pregnant after treatment	11	12	10	2	35
% successful	69	31	34	22	38

Only those with a fertility index below 30 are included in this table (first two columns in table I)

TABLE III—PRE TREATMENT QUALITY OF SEMEN IN 93 MEN WITH FERTILITY INDEX BELOW 30

Quality of semen before treatment	No of men	No of wives pregnant after treatment
Density never exceeding 20 million per ml	36	13
Motility adjusted for age of specimen, equivalent to less than 10% three hours after ejaculation	39	14
Morphologically normal sperm below 35%	36	15
At least one character always below the above standards	78	29
Best value above these standards	15	6

testosterone considerably increased the couple's chances of success It is perhaps worth mentioning that in an appreciable number of cases, according to statements from both partners, the husband's coital performance was improved

To ascertain as nearly as possible whether the treated and untreated series are comparable so far as their degree of infertility was concerned, the couples in each series, where the husband's fertility index was below 30, have been grouped according to their number of years' barrenness with unprotected coitus In the methyltestosterone series this period was reckoned to extend up to the start of the husband's treatment with methyltestosterone In the controls, where methyltestosterone was not given, it was taken as extending to the date when the wife's investigation and treatment began In both series years of barrenness were reckoned from when unprotected coitus started after marriage or (in cases where there had been a previous pregnancy) after the most recent pregnancy Table II shows that the two series compare well, so far as their infertility is concerned

Change in Quality of Semen

Analysis of the quality of the semen has been confined to the 93 cases with a fertility index below 30

For those unfamiliar with the grading of semen by fertility index, table III indicates the pre treatment quality of the semen of this group of men It is based on the highest value found in the ejaculates tested

Only 48 of the 93 patients sent semen for testing after they had had some treatment, but 17 (35%) of these produced pregnancies and can therefore be regarded as a fair sample of the cases under consideration, the pregnancy rate for the whole group being nearly 38%

The change in quality of the semen is shown in the accompanying figure Of the 23 cases showing improvement in their fertility indices 8 men had a post treatment index of over 40, and 6 others of between 30 and 40 The remaining 9, though significantly better than before treatment, still had an index under 30

The following case illustrates the relation between methyltestosterone therapy and improved quality of semen

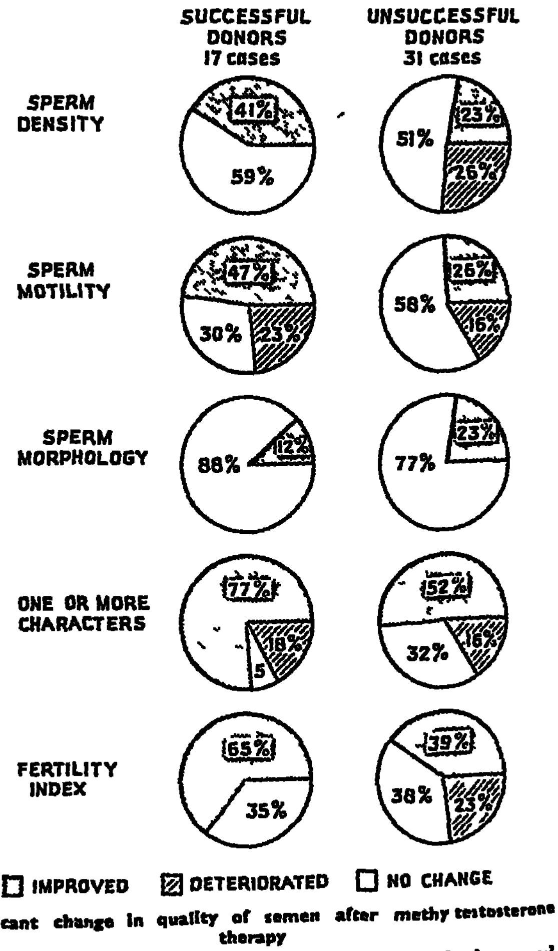
The couple were first seen in September, 1950, and the husband sent two ejaculates which had fertility indices of 25 and 26 He was then given intermittent methyltestosterone therapy, and in February, 1951 after three months' treatment, the fertility index of his semen was 41 Shortly after this, owing to family difficulties treatment was discontinued for six months In January, 1955, before treatment was recommenced, the fertility index of the husband's semen had gone down to 18 After four months renewed treatment his semen scored 63 and shortly after this last test his wife became pregnant

As is clearly shown in the figure, there are proportionately more instances of improvement in the semen of the men whose wives subsequently conceived than in the semen of those who had no success The only deterioration in semen quality observed among the successful donors was a fall in the percentage motility of the sperm, without a compensating rise in sperm density, in 4 cases, and in 2 of these the semen was not tested until after the wife had become pregnant, and two to three months after the husband had stopped taking tablets

The preponderance of cases showing improved quality of semen among the men whose wives became pregnant, compared with the unsuccessful series, is not statistically significant Had the whole group of 93 men sent post treatment semen for examination, and had the results observed on the 48 men who did so been found to hold good for the other 45, the difference between the two series would have been significant

Volume of Ejaculate

There was no indication that treatment with methyl testosterone affected the volume of the ejaculate appreciably In 3 cases (2 of which had a fertility index over 30) the volume of the ejaculate before treatment was persistently below 1 ml, and treatment was given mainly in the hope of increasing the quantity of semen produced In 2 of these cases there was no change after treatment, and in the 3rd, although the volume was nearly double that of the largest pre treatment specimen, it was still less than 1 ml



Significant change in quality of semen after methy testosterone therapy

Improvement is always assessed against the higher, and deterioration against the lower, pre treatment value Change in density, motility, or morphology is regarded as significant if the post treatment value differs from the appropriate pre treatment value by more than 20% of this value

Change in the fertility index is regarded as significant if the post treatment value differs by 10 or more from the appropriate pre treatment value. If the fertility index of the better pre treatment *specimen* is less than 5, a change of 5 is regarded as significant

In the group "*one or more characters*" deterioration means a fall in the value of one character, with no improvement in any

Fructose and Citric-acid Content of Semen

The fructose and citric-acid levels in the semen were estimated before and after treatment in 43 cases, including 15 in which pregnancy followed treatment In view of the work of Mann et al (1949) it seemed possible that men with low levels of these substances might have low androgen levels and therefore benefit from treatment with methyltestosterone, but there was no indication that low pre-treatment levels of either or both substances were related to response to treatment, nor did treatment produce any significant change in their levels in the semen There was, however, some suggestion that the ratio of the quantity of citric acid to the quantity of fructose in the ejaculate increased with treatment, and this change was more common in the successful than in the unsuccessful series Our recent work (unpublished) on partitioned ejaculates indicates that such a change is the result of an increase in the proportion of prostatic secretion in the ejaculate and of a corresponding decrease in the vesicular contribution Semen of good quality tends to contain proportionately more prostatic fluid than that with lower potential fertility, hence the observed increase in the citric-acid/fructose ratio in the semen of men taking methyltestosterone may well be associated with improvement in its fertilising-power

Discussion

The degree of improvement in semen after methyltestosterone therapy is seldom from very poor to good but rather from poor to fair or from fair to average As shown in the figure, the character least susceptible to improvement is the morphology of the sperm, and the proportion in the sperm population of those types of head-form such as pear, pyknotic, and multiple, which are known to arise in the testis (Harvey 1955), is almost unaltered after treatment Considered in conjunction with the fact that maximum improvement is often reached in three months or less, this suggests that the beneficial effect of the methyltestosterone is probably due to improved functioning of the epididymis and vas, and to more efficient ejaculation, and not to any fundamental improvement in spermatogenesis

The results observed in this series of cases can be explained by such an effect Better nourishment of the sperm in the epididymis and more efficient evacuation of mature sperm at coitus would result in improved motility, and, where sperm production in the testis is high, in increased density Where sperm production is low the elimination of accumulated postmature sperm from the ejaculate would tend to produce fewer sperm, with an improved percentage motility, a condition observed in several cases Where, however, the poor motility before treatment is due to defective development of the spermatozoa, percentage motility will not be improved by treatment with methyltestosterone, although the density may be, and the ejaculate would then actually contain more normal motile sperm, but these would represent the same proportion of the sperm population

On this view, treatment with methyltestosterone is not a cure for inherent testicular deficiency but a stimulus which enables the husband to produce the best ejaculate of which he is capable The timing of the dosage produces this stimulus at the period when the wife is ovulating By discontinuing the treatment in the latter part of the wife's menstrual cycle the potency of the stimulus is retained, and pituitary secretion is not depressed, as it would tend to be if the treatment were given continuously

Summary

Methyltestosterone was given to the husband in 93 cases of subfertile marriages in which the semen has a fertility index below 30 In 35 of these cases (38%) the wife became pregnant within two years

The success of this treatment was measured by comparing the number of pregnancies produced with that of 141 control couples in which the fertility index of the husband's semen had the same range but where he was not so treated In these cases 24 (17%) of the wives became pregnant

Analysis of the improvement in the semen after treatment of the husband with methyltestosterone shows that this hormone is not a cure for inherent testicular deficiency but a stimulus to produce the best possible ejaculate For this reason it should be given to the husband at such a time that it produces the stimulus when his wife is most likely to be ovulating During the remainder of the menstrual cycle it should be withheld so as to prevent depression of the pituitary gland and to retain the potency of the stimulus

MECAMYLAMINE ILEUS AS A SURGICAL EMERGENCY

ALAN P GRANT
M.D Belf, F.R C.P I, M R C P
PHYSICIAN

JOHN S BOYD
M B Belf, F R C S E
SURGEON

DOWNE HOSPITAL, DOWNPATRICK, NORTHERN IRELAND

THE use of ganglionic-blocking agents is becoming increasingly common in the treatment of hypertension. Recently mecamylamine hydrochloride ('Inversine'), a secondary amine, has been introduced as an improvement on the quarternary ammonium compounds hexamethonium and pentolinium The advantages claimed for this drug are complete oral absorption and more consistent control of the blood-pressure

In a single month we saw 2 patients presenting as acute surgical emergencies, owing to ileus arising from mecamylamine therapy

Case-reports

Case 1 —A man, aged 49, was admitted to hospital with suspected bowel obstruction His doctor stated that he had been under treatment for hypertension (blood pressure 200/120 mm Hg) Twelve days previously a course of mecamylamine therapy had been started, the initial dose was 5 mg b d for six days and thereafter 5 mg t i d After four days on the latter dosage the patient complained of obstinate constipation, generalised crampy abdominal pain, and vomiting The mecamylamine therapy was then discontinued In the next thirty six hours several doses of neostigmine was administered, and enemas were given, without result After this the abdomen began to swell and it became much distended No urine was passed, but, as the bladder was not distended, it was felt that this was due to the repeated vomiting

Examination

On admission the patient was thin, slightly cyanosed, with a dry furred tongue and breath smelling strongly of acetone Temperature 97°F, pulse rate 100 per minute, blood pressure 145/100 mm Hg On abdominal examination there was an old appendicectomy scar The abdomen was much distended and tympanic, with slight shifting dullness in both flanks, no tumour palpable, and no localised tenderness, a few high-pitched bowel sounds on prolonged auscultation The patient vomited dark brown fæcal-smelling material several times Serum potassium 6 7 m eq per litre Straight X-ray of the abdomen showed several air fluid levels in the small bowel Barium enema showed several diverticula in the pelvic colon but no definite evidence of a large bowel lesion, although there was a suspicious stricture-like area in the descending colon After evacuation, there was retrograde filling of one of the dilated loops of small bowel

Diagnosis and Treatment

Clinically, the diagnosis was thought to be between paralytic ileus and mechanical obstruction low in the small bowel or in the colon As the patient was markedly dehydrated, it was decided to try conservative treatment for a time An intravenous drip of saline solution was set up, and administration of penicillin and streptomycin started A Ryle's tube was passed and the stomach aspirated half-hourly Three doses of neostigmine 1 ml, followed by enemas, were given, but neither flatus nor fæces was passed After twelve hours of this treatment the patient's general condition had improved slightly, but the abdominal distension had increased, and, as there was still a good deal of foul fluid coming up the Ryle's tube, it was decided to operate

Operation and Course

On opening the abdomen through a lower midline incision a good deal of clear free fluid was found The small bowel was much distended down to the ileocæcal junction The cæcum and ascending and transverse colons looked normal The descending colon was collapsed from the splenic flexure down to the pelvirectal junction, but there was no evidence of vascular impairment and a thorough search of large and small bowel revealed no evidence of tumour or other cause of obstruction The abdomen was closed

Intravenous fluids, gastric suction, and chemotherapy were continued postoperatively, and forty eight hours after operation (four days after cessation of mecamylamine therapy) the patient had a bowel action and passed flatus

By the fourth postoperative day the distension had almost disappeared, the bowels were acting normally, and the patient was taking a light diet without nausea Unfortunately, on the fifth day, he had a presumed coronary thrombosis or pulmonary embolism and died almost immediately

Case 2 —A man, aged 60, had been in a medical unit from July 1 to 20, 1956, when he was given mecamylamine therapy for hypertension There was a long history, over ten years, of angina and cardiac asthma His general condition was good and blood-pressure on admission 240/120 mm Hg Full investigations excluded secondary hypertension Urea-clearance 57% of normal, specific gravity range of urine 1008–1015, blood urea 59 mg per 100 ml, constant slight albuminuria, intravenous pyelography showed moderate concentration He was having mecamylamine 27 5 mg daily, in divided doses, on discharge from hospital, and his blood pressure averaged 200/105 mm Hg He was readmitted to a surgical unit on the third day after leaving hospital as a case of possible mesenteric thrombosis or intestinal obstruction He complained of severe generalised abdominal pain of twenty four hours' duration and had vomited black fluid He had hiccup and had been constipated two days

Examination

On admission the patient seemed to be in pain and had a very dry mouth, temperature 98°F, and the pulse rate 70 per minute blood-pressure 240/100 mm Hg The abdomen moderately distended but not tender, bowel sounds very infrequent and high pitched He had had a total of 287 5 mg of mecamylamine over thirteen days, and this drug was discontinued Straight X ray of the abdomen showed much distension of the small intestine suggesting intestinal obstruction

Treatment and Progress

A conservative policy was decided on, and the patient was given an enema with good result By the next day his abdomen was much less distended, bowel sounds very faint but more normal in pitch He had recovered completely from the ileus by the third day, when the bowels worked normally

Discussion

In both the present cases occasional high-pitched bowel sounds were associated with severe flatulent distension of the abdomen but no tenderness Pain was a presenting symptom, and despite the history this led to suspicion of mechanical obstruction

Constipation is a well known complication of ganglionic blocking drugs Freis et al (1952) noted constipation in at least two-thirds of a series of hypertensives treated with hexamethonium, and, in addition, 4 definite cases of paralytic ileus were noted In milder cases of ileus there is abdominal distension with absence of bowel sounds, such cases usually respond to conservative treatment with an enema and parasympatheticomimetic drugs (Campbell and Robertson 1950, Lyons and Lord 1951), but deaths have been reported (Mackey and Shaw 1951, Thomas and Williams 1951)

Abdominal pain associated with intestinal distension is sometimes met with and an acute surgical emergency is simulated, as in both our cases These symptoms may suggest an obstruction so that operation is performed, as in our 1st case

Goldstone (1952) felt himself forced to do a laparotomy in similar circumstances on a patient receiving pentamethonium He found the small gut distended, while the cæcum and colon were normal in calibre The small gut, after deflation, remained flaccid and did not contract as it does after relief of the distension due to mechanical obstruction His patient died after operation

Bourne and Hosford (1951) report that at operation on a patient receiving hexamethonium in whom obstructive symptoms developed, they found œdema with distension of the small bowel but no obstruction

McCalla et al (1953) reported 2 cases of hexamethonium ileus They operated on 1 case and found the proximal small intestine and colon dilated but the distal small bowel completely collapsed This patient died, while the other patient, treated with intestinal suction and enemas, lived

Although operation on a case of mecamylamine ileus has not, as far as we know, been described there is no reason to consider this drug different in its essential action from the hexamethonium group In our laparotomy case there was collapse of the descending colon while the small bowel was much distended

It is difficult to explain these findings Motor stimulation of the intestine is generally considered to be the function of the parasympathetic system, whose preganglionic fibres terminate in the intramural plexuses, yet vagotomy does not have a pronounced effect on intestinal activity in laboratory animals

Faik et al. (1950) proved a slight decrease in tone and in the number and duration of peristaltic waves, and Alvarez (1948) clearly indicated that in man the most readily demonstrated effect was on gastric function. Sympathectomy on the other hand has little effect on the gastro intestinal tract (Craig et al 1950)

Probably the ganglionic blocking drugs act on the bowel through the intramural plexuses Locket (1951) suggested that, as ileus after hexamethonium followed only oral medication, the effect was local and associated with poor absorption and high concentrations in the gut, otherwise paralytic urinary symptoms would be expected Accumulation in one section of bowel might lead to complete arrest of both absorption and peristalsis, while the following section might show in some cases an increase in non propulsive motility and decrease in propulsion leading to pain Code et al (1952) considered at least four types of intrinsic motor activity which perform different functions—propulsion, mixing, and absorption

It would not seem necessary, therefore, to consider the action of hexamethonium outside the intestinal wall to explain why it may give rise to ileus Mecamylamine on the other hand is stated to be completely absorbed (*Lancet* 1955) *It is more difficult, therefore*, with this drug to explain the findings satisfactorily, as one would expect with high blood concentrations an overall effect on the intestine The finding of occasional high-pitched peristalsis suggests that some types of intestinal waves are still present although these are not propulsive

Summary

In 2 cases mecamylamine therapy for hypertension led to ileus mimicking intestinal obstruction

In such cases a history of recent treatment with anti-hypertensive drugs, and the finding of occasional high-pitched bowel sounds, should suggest the diagnosis

This complication should be treated conservatively

Administration of ganglionic-blocking agents should be strictly controlled, especially if renal function is impaired.

We wish to thank Mr J. C Robb and Mr R P. Smyth for their help and interest in the management of these cases

URINARY EXCRETION OF INDIVIDUAL CATECHOL DERIVATIVES

STUDIED BY A CHEMICAL METHOD

MARY MCMILLAN
M.D , Ph.D Leeds, B.Pharm. Lond.
LATE REGISTRAR IN CLINICAL PATHOLOGY, ROYAL INFIRMARY, SHEFFIELD.*

BY this method the catechol derivatives are adsorbed on to alumina and, after elution, are separated from one another by paper chromatography. The amounts present are assessed semiquantitatively by the fluorescence of their buffered oxidation products in ultraviolet light. Noradrenaline, adrenaline, hydroxytyramine, and dihydroxyphenylacetic acid have been detected by this method, which may be used for screening suspected cases of chromaffin tumour.

Methods

Preparation of Urine Extract

Urine is collected for 24 hours, and 15 ml of 10% sulphuric acid is added to it to ensure that the final pH is 3 5 or less. The urine is thereafter kept refrigerated until processed, which must be done within the next few days.

The preliminary procedure of adsorption on to alumina is a modification of that of Von Euler and Orwen (1955) 500 ml. of the urine, clarified if necessary by filtration is treated in a large beaker with 12 5 g of alumina (B D H , 'for chromatographic purposes') While the mixture is being vigorously stirred, 10 N sodium hydroxide is rapidly added drop by drop until the liquid, free from foam, reaches a pH of 8 7 shown by test paper (Johnson of Hendon no 8410) The end point is well defined and it is unnecessary to use a pH meter Stirring is continued for 4 or 5 minutes during which time it is usually necessary to add one or two drops more of 10 N sodium hydroxide to keep the mixture at pH 8 7

The alumina is then collected by filtration with a Buchner funnel 7 5 cm. in diameter and Whatman paper no 541, the alumina in the beaker being kept suspended to facilitate rapid filtration The time of exposure to unfavourable pH values is kept as short as possible and must not exceed 15 minutes The alumina is washed twice with quantities of 10 ml. of distilled water added to the Buchner funnel The alumina is then transferred as quantitatively as possible from the Buchner funnel to a small beaker (150 ml) without the filter paper being displaced from the funnel, and 8–10 ml of 0 5 N sulphuric acid is added to the beaker to elute the catechols. After it has been stirred for a minute the alumina is filtered off in the Buchner funnel with the same paper as before This procedure of elution is repeated twice more To the combined opalescent eluates having a pH of 2 or less is added drop by drop and with constant agitation 10 N sodium hydroxide to about pH 3 followed by about N sodium hydroxide to pH 4 0 shown by indicator paper. The solution with precipitate is then equally distributed into three 50-ml centrifuge tubes which are then filled with a mixture of equal parts by volume of ethanol AnalaR and acetone AnalaR, the filtration flask being well washed out with the solvent mixture After being stirred the mixtures are refrigerated for half an hour, and the flocculent white precipitate is removed by centrifuging The precipitate is washed with a few ml of acetone-ethanol mixture

The supernatant fluids, together with the washings, are in turn transferred to a 100 ml conical flask and distilled at reduced pressure under a stream of nitrogen at a bath-temperature of 40°C The level of the liquid is kept above that of the bath, and the flask is removed as soon as the contents are dry (Goldenberg et al 1954)

The distillation head and side of the flask are washed down with about 5 ml. of a mixture of 1 part of N hydrochloric acid in 100 parts by volume of acetone AnalaR, and this liquid is allowed to extract the residue in the flask for about 5 minutes before the faintly straw-coloured solution is transferred to a small tube graduated at 0 5 ml

The extraction is repeated three times more, the deposit being broken up if the flask is heavily encrusted. The successive extracts are evaporated down to the gradation mark under a stream of nitrogen. The tube is refrigerated, and any precipitate is removed by centrifuging at the time of preparation of the chromatogram.

Chromatography

Sheets of Whatman paper no 1 measuring 25 × 33 cm. are marked into ten vertical strips each 2 5 cm. wide, and a horizontal line is drawn a few cm. above the lower edge to mark the origins of the ascending chromatograms On each paper seven strips may conveniently be allocated to serial dilutions of one extract of urine, the remaining three being reserved for standard solutions

All additions are made from a 0 02 ml pipette specially prepared from 5 mm. external diameter 'Pyrex' capillary glass tubing drawn out to a diameter of 2 mm. at the tip and filed with carborundum. Such a pipette was made to deliver 0 25 µl. per drop.

Solutions are added to the paper drop by drop to cover the central 1 8 cm. of each strip, the row of drops being dried by cold air from an electric hair drier before the next row is applied In this way an even band not exceeding 4 mm. in width is obtained

A suitable preliminary range of quantities to apply for most urines is 0·001–0 040 ml. of the 0 5 ml. extract Standard solutions of *dl* adrenaline bitartrate (B.D H) and 3 hydroxytyramine (Light) are prepared in 0 01 N hydrochloric acid, each containing 1000 µg of the free base per ml., such solutions are kept at 4°C and renewed at intervals Noradrenaline is obtained as ampoules of the bitartrate ('Levophed,' Bayer), a fresh ampoule being opened on each occasion. Equal parts of the three standards are mixed, diluted in a mixture of equal parts of ethanol AnalaR and acetone AnalaR, and added to the paper in amounts of 0·1, 0 2, and 0·3 µg of each catechol derivative

As soon as they are prepared the paper sheets are threaded on a glass rod and suspended in a chromatogram tank measuring 28 × 26 5 cm. with a height of 38 cm. The solvent system is phenol saturated with water and sulphur dioxide added to the tank to a depth of about 1 cm, from a separating funnel immediately before use The tank is sealed and left in an unheated insulated box or cupboard overnight The solvent ascends 23–29 cm.

Spraying of Chromatogram

The papers are withdrawn from the tank and freed from much of the phenol by agitation in a dish containing 750 ml of benzene AnalaR After hanging in air for a few minutes the papers feel dry and are sprayed without delay using an all glass spray containing nitrogen from a cylinder. The spray solution buffered at pH 5·9 and made up freshly each day, has the following composition 36 ml of 0 66 M potassium dihydrogen phosphate 4 ml of 0 66 M disodium hydrogen phosphate 4 5 ml. of 6 6% potassium ferricyanide solution, and 5 ml of 40% formaldehyde solution preserved over calcium carbonate

Band C	0 202		,,	Red ,, brown yellow	Yellow

* As described in text † Shepherd and West (1951)

Care is taken to saturate the paper but not to allow any running Any red or purple areas appearing at this stage are noted The paper is immediately hung inside an oven at 110–120°C and left there for exactly 5 minutes, after which it is inspected without delay in ultraviolet light A 'Mazda' lamp MBW/U in a metal case has been found suitable The spots of yellowish green fluorescence are most readily seen by transmitted light The sites and intensities of the spots of both standards and urine extract are recorded immediately because they fade appreciably after a few minutes

The adrenaline and noradrenaline standards should be just visible at a level of 0 1 μg, whereas hydroxytyramine is usually seen at a lower limit of 0 2 μg and dihydroxyphenylacetic acid at 0 5 μg Quantities as great as 1 5–2 0 μg of the catecholamines are visible as red or purple areas, and the fluorescence of such amounts remains visible for many weeks

Identification of Individual Catechol Derivatives

Identification is made by the R_F value (table I) and by comparison with the standards There is clear cut separation of all derivatives found in urine, except that very occasionally the spot of dihydroxyphenylacetic acid may be indistinguishable in position from that of adrenaline, which, however, is not usually detectable in urine If this happens, the following alternative method of identification allows the recognition of relatively large amounts of adrenaline, such as might be expected in some cases of chromaffin tumour

Three chromatogram strips are prepared as before from 1 0 μg of adrenaline standard, an amount of the urine extract calculated to contain at least 1 0 μg of the supposed adrenaline, and the same quantity of urine extract with the addition of 1 0 μg of adrenaline standard These three strips are developed according to a modification of the method of Pitkanen (1954) First the strips are sprayed with a solution composed of 36 ml of 0 66 *M* potassium dihydrogen phosphate, 4 ml of 0 66 *M* disodium hydrogen phosphate, and 4 5 ml of 0 1 *N* iodine solution After a few minutes, during which the papers are best dried under a stream of cold air, they are resprayed with a solution consisting of 4 g of *p* dimethyl aminobenzaldehyde in 380 ml of ethanol and 80 ml of concentrated hydrochloric acid Adrenaline gives a red colour with iodine, and this is subsequently changed to a distinctive blue violet at a level as low as 1 0 μg Dihydroxy phenylacetic acid first bleaches the iodine but does not give any colour with Ehrlich's reagent

Results

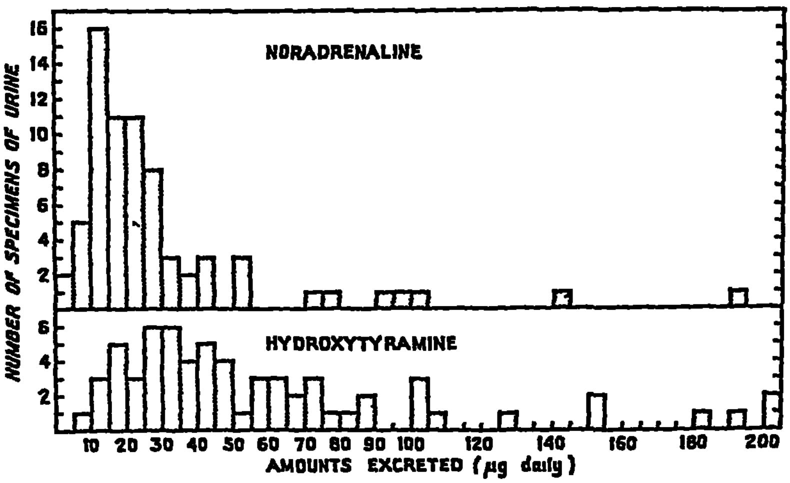
Eighty-five specimens of urine from 66 patients with either paroxysmal or sustained hypertension and specimens from 20 other persons, including some healthy people, were examined Only 1 case of chromaffin tumour was discovered (McMillan 1956)

Noradrenaline

The noradrenaline excreted in seventy one specimens of urine from 65 patients with either paroxysmal or sustained hypertension not associated with chromaffin tumour ranged from less than 5 μg to 190 μg daily (see figure) Ten specimens (14%) contained 50 μg or more daily and only three specimens (4%) 100 μg or more daily In 1 patient an output of 140 μg was associated with malignant hypertension, two specimens collected after sympathectomy showed only 24 and 44 μg of noradrenaline, the blood-pressure then being much reduced A high output of 190 μg daily was found in a case diagnosed as a hypochondriacal anxiety state, there was only 1 other patient with this condition, and in that patient the noradrenaline excretion was 95 μg daily The third highest output, 100 μg daily, was associated with severe essential hypertension None of these 3 patients was re examined, but a hypertensive excreting 90 μg daily was found on a subsequent occasion to excrete less than 30 μg 5 at least of this series were said to give positive phentolamine tests In several of the most severe cases of hypertension the patients excreted only small amounts of noradrenaline

Seven specimens of urine from the patient in whom a chromaffin tumour was confirmed at operation contained 124, 360, 370, 490, 600, 1000, and 1015 μg of noradrenaline daily, all but one of these values being much greater than any found in the rest of the series

Recorded in μg per 100 ml of urine the



Catecholamine content of unhydrolysed urine of hypertensives noradrenaline excretion of 66 patients with either paroxysmal or sustained hypertension not associated with tumour was 0 3–15 μg Seven specimens (10%) contained 5 μg or more per 100 ml. and only one specimen (1%) more than 10 μg per 100 ml The seven specimens from the patient with phæochromocytoma contained 15, 21, 40, 51, 73, 74, and 114 μg per 100 ml Non-hypertensive and healthy persons (20 people) excreted up to 64 μg daily, the urine containing 0 3–6 μg. per 100 ml

Hydroxytyramine

In sixty-four specimens of urine from 58 patients with either paroxysmal or sustained hypertension not associated with tumour the excretion of hydroxytyramine ranged from less than 10 to 200 μg daily, twenty-seven specimens (42%) contained 50 μg or more daily, and eleven specimens (17%) more than 100 μg daily (see figure) With 2 exceptions an excretion of more than 70 μg of noradrenaline daily was associated with an excretion of 150 μg or more of hydroxytyramine daily, and only 1 of the 6 patients excreting 150 μg or more of hydroxytyramine daily excreted less than 77 μg of noradrenaline (the amount in that case was 29 μg) The specimens from the patient with phæochromocytoma contained 50, 70, 92, 95, 180, 250, and 450 μg daily This relatively small increase is remarkable because the tumour contained mainly hydroxytyramine and relatively little noradrenaline The excretion of hydroxytyramine by 58 patients with either paroxysmal or sustained hypertension not associated with tumour was 0 5–18 μg per 100 ml Twenty-four specimens (41%) contained 5 μg or more per 100 ml, and nine specimens (14%) 10 μg or more per 100 ml The patient with phæochromocytoma excreted 6, 8, 8, 10, 18, 25, and 30 μg per 100 ml, and normotensive persons 0 1–10 μg per 100 ml urine

Adrenaline

Adrenaline could not be detected with certainty by its fluorescence in any of the specimens from either normotensive or hypertensive patients, corresponding to an output of less than 0 5–1 0 μg. per 100 ml in most cases It was not detected in the urine or the tumour of the patient with phæochromocytoma

TABLE II—URINARY EXCRETION OF CATECHOLAMINE IN CERTAIN HYPERTENSIVE AND METABOLIC DISEASES

Disease	Age (yr)	Sex	Noradrenaline excretion		Hydroxytyramine excretion		Adrenaline excretion	
			μg daily	μg per 100 ml.	μg daily	μg per 100 ml	μg daily	μg per 100 ml

The values are only approximate, being correct within ± 25%

Catecholamine

Table II shows the findings in some special hypertensive states and metabolic disorders

Other Catechols

Two bands, A and C, are regularly present in urine chromatograms, a third band, B, was discovered in the urine of the patient with phæochromocytoma Some of their characteristics are listed in table I

Band A is identifiable as 3, 4 dihydroxyphenylacetic acid by R_F value and colour reactions No systematic assays were made of this substance, but it was often present in considerable amounts, which were, however, usually rather less than those of hydroxytyramine

Band B was second in prominence only to the band of noradrenaline in the urine of the patient with phæochromocytoma but was not identified with certainty in other urine though occasionally a weak fluorescent band did appear at this site Its properties (table I) and its reactions with ninhydrin, diazotised *p* nitro aniline, and potassium-dichromate solutions show it to be closely related to noradrenaline and hydroxytyramine It oxidises to a melanin like substance On incubation of a suspension of guineapig liver with noradrenaline, hydroxytyramine, and adrenaline separately and subsequent purification of the catechols by adsorption on to alumina and chromatography it was found that a substance indistinguishable from band B was present among the derivatives of adrenaline and noradrenaline but not of hydroxytyramine It was never traced in urine to which large amounts of known catecholamines had been added at any stage during concentration A catechol derivative with an R_F similar to band B (Crawford 1951) is *α* ethyl noradrenaline, but this substance has not yet been investigated

Band C must be carefully distinguished from noradrenaline It is almost always present and is sometimes very prominent, amounting to the equivalent of 200 μg of noradrenaline daily The amount does not appear to correlate with that of noradrenaline and hydroxytyramine in the urine of either normal or hypertensive people, and relatively little was present in any of the specimens from the patient with phæochromocytoma The band was never produced by adding known catecholamines to urine or by treating them with organic solvents or exposing them to alkali The substance forming band C is not precipitated by barium hydroxide solution at pH 5 and is not adsorbed on to ion exchange resin 'IRC 50' It is not destroyed by acid hydrolysis at pH 1 0 Although its R_F resembles that of 3, 4 dihydroxyphenylserine, unlike this substance it has not given any colour reaction with ninhydrin Catecholglycollic acid would probably have a higher R_F than has band C

Discussion

A simple chemical method of detecting increased urinary excretion of catecholamines by patients with phæochromocytoma has been urgently wanted The symptoms of phæochromocytoma are varied and mimic those of other diseases No reliable diagnostic test with a sympatholytic drug is yet known, and drugs stimulating secretion of the tumour carry a grave risk to the patient Assay of the urine is the most valuable procedure, biological assay, which has almost always to be used, has obvious disadvantages, and simplifications introduced into the method lead to further loss in specificity and to the risk of false results Chemical assays previously published depend entirely on fluorimetry of a solution containing a mixture of catechols The disadvantages of this are that the equipment required limits the practicability of the assay to a few centres, and the fluorescence is not specific for any one catecholamine and is liable to be affected by the presence of other substances

The fluorescence methods fall into two groups those depending on the reaction of ethylene diamine with the catechol group, and those depending on the formation of fluorescent derivatives on oxidation Von Euler et al (1955) reported that the ethylene diamine method of Natelson et al (1949) gave for urinary catechols calculated as noradrenaline values which were 10–100 times those obtained biologically, the results with hydrolysed urine being even worse Such interference was attributed to acidic catechols formed by degradation

Weil Malherbe (1956) assayed the hydroxytyramine of alumina adsorbed urine by subtracting the sum of the values obtained for noradrenaline and adrenaline by the methods of Lund (1950) or of Von Euler and Floding (1955b), which measure the fluorescence of catecholamine oxidation products, from the values obtained by the ethylene diamine method (Weil-Malherbe and Bone 1953), a necessary preliminary being the separation of acidic from basic catechols on ion-exchange resin This method is unsatisfactory in that it involves many manipulations and depends on the complete removal of all acidic catechols and on a complete lack of fluorescence of hydroxytyramine on oxidation, in accordance with the concept that only compounds with the side chain containing a β OH group and a H at the α C atom can fluoresce appreciably in the reaction Von Euler and Floding (1955a) stated that hydroxytyramine did fluoresce weakly and reported (Von Euler and Floding 1955b) some discrepancy between biological and chemical assays for which the reason was unknown

In the present method catechols such as dihydroxyphenylacetic acid and even protocatechuic acid gave oxidation products of similar colour and fluorescence as did true catecholamines treated with buffered ferricyanide solution The inference must be drawn that no assay using a mixture of catechols can be relied on

Burn and Field (1956) describe a chemical method using ethylene diamine for the diagnosis of phæochromocytoma Urine from healthy people gave extinction values in colorimetry which were equivalent to as much as 50 µg of noradrenaline per 100 ml of urine, the same extract showing less than 5 µg per 100 ml by bio-assay These workers recommend that urine with higher extinctive values than this should be submitted to biological assay for confirmation of phæochromocytoma No mention was made of hydroxytyramine

Chromatographic separation is more satisfactory with phenol water sulphur dioxide than with n-butanol acetic acid water (4 1 5) When adrenaline and noradrenaline were chromatographed in the former solvent and the paper was then cut horizontally at 1-cm intervals, the catecholamine content of each strip being determined by a quantitative method with phospho tungstic acid reagent (to be published), the recovery of noradrenaline averaged 91 7% in seven determinations (range 84–102%, standard deviation 5 49) and of adrenaline 96 4% in nine determinations (range 87–112%, standard deviation 6 85) The figures for hydroxytyramine were similar Omission of sulphur dioxide or substitution of phenol 0 1 *N* hydrochloric acid reduced the yield of adrenaline to 29–62%

Similarly, quantitative assays showed that the recovery of catecholamines added to urine which was then adsorbed on to alumina, concentrated, and chromatographed was 90% for noradrenaline and 85% for adrenaline The alumina has been found to vary, and it is advisable to check every new batch

The original spray solution of Shepherd and West (1953) proved unsatisfactory in that the fluorescence faded very rapidly as melanin derivatives were formed, and hydroxytyramine often did not fluoresce at all Of several buffer systems investigated, phosphate at pH 5 9 proved best because very small amounts of the catecholamines were visible and both the red colour of the oxidation products and the fluorescence were visible for many weeks

The method described here is relatively rapid, a result can be obtained in little more than 24 hours from receipt of the specimen Its chief disadvantage is that fluorescence is measured arbitrarily by visual comparison with standards and the results are only partially quantitative Against that, the individual catecholamines are assessed separately, and the method has shown that no less than six catechol derivatives may be excreted in the urine

Summary

A method is described for the separate assessment in urine of the following catechol derivatives noradrenaline, adrenaline, hydroxytyramine, and dihydroxyphenyl acetic acid

Two unidentified substances were found one occurred regularly in all urine, often in large amount, the other was present in very great amount in a case of phæo chromocytoma

The method requires no expensive apparatus A result may be obtained in little more than 24 hours

The results of the assay of 105 urine specimens from hypertensive and other persons are presented

I am much indebted to Prof F S Fowweather and Dr A Jordan for their interest and encouragement, Dr Jordan for his careful criticism of this paper, the many clinicians of the United Sheffield Hospitals and elsewhere for their cooperation, Dr H Blaschko for the gift of 3, 4 dihydroxyphenyl serine, Dr G B West for epinine, and Dr R Dahlbom, of Astra Ltd, for 3, 4 dihydroxyphenylacetic acid

UTERINE ELECTROLYTES IN PREGNANCY AND LABOUR

R L Cort
M D Yale
INSTITUTE FOR MOTHER AND CHILD CARE

J H Cort
M D Yale, Ph D Camb
INSTITUTE FOR CARDIOVASCULAR RESEARCH,
PRAGUE, CZECHOSLOVAKIA

It is generally accepted that potassium deficiency is associated with hypofunction of both striated and smooth muscle, leading, for example, to paralytic ileus Pregnancy introduces to the maternal organism two new factors which tend to drain more potassium than usual from the body the storage of minerals in the fœtus, and the increased production of steroids, which might lead to renal loss of potassium Furthermore, intense muscular work and possibly anoxia may lead to a local loss of potassium from the cells of the myometrium, if this loss is not made good it will inevitably affect further contraction (Szent Gyorgi 1951) We therefore tried to follow changes in intracellular electrolytes and water in the myometrium during pregnancy and labour (especially prolonged inefficient labour) in groups of patients sufficient for statistical analysis though small

Methods

All the material was collected during uterine surgery for other reasons Blood was withdrawn for analysis usually just before *operation* Since local trauma may lead to loss of potassium from cells, care was taken to take the biopsy specimens rapidly from fresh tissue. Samples of skeletal muscle were taken from the rectus abdominis muscle during laparotomy, and myometrial samples were taken from the outer muscle layers in the lower uterine segment. In all the cases the anæsthetic used was ether.

The patients were selected so as to exclude obvious metabolic disturbances—e.g., diabetes mellitus, congestive heart-failure, and toxæmia—which might influence the composition of the tissues. A control group of 10 patients undergoing hysterectomy was selected for base-line non-pregnant values. In no case was there any reason to believe that any local pathology had influenced results in the controls, but the indications for hysterectomy meant that the controls were older than the pregnant women, although we tried to counteract this as much as possible by selecting patients aged 46 years or less.

A second group of pregnant women was selected consisting of patients who underwent cæsarean section for either disproportion or placenta prævia 2 to 3 weeks before the onset of labour was due, to illustrate the myometrial changes due to pregnancy alone.

A third group consisted of patients in ineffective active labour who had to undergo cæsarean section usually because of disproportion and failure to engage at a trial of labour. All of this group had been in active labour for at least 6 hours, and would presumably illustrate the effects of extreme muscular contraction on the composition of the myometrium. A fourth group consisted of 10 women with prolonged ineffective labour, who had not reached full cervical dilatation in 36–72 hours of labour and whose contractions were judged to be infrequent, ineffective, or abnormal. All of them had already had their membranes ruptured either naturally or manually and had received 'Pitutrin' without the desired effect. Cæsarean section was indicated for the safety of both mother and child.

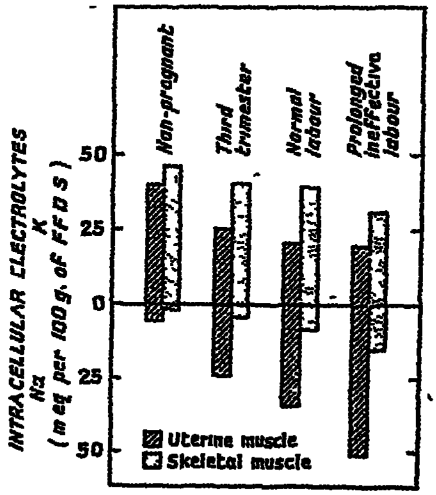
Every attempt was made during the course of labour to maintain an adequate intake of calories and fluids to prevent dehydration.

Analytic Methods.—The tissue samples were rapidly blotted of excess blood, obvious fat was quickly removed, the samples were placed in weighing flasks, and their fresh weights were determined. They were then left to dry overnight in a drying-oven set at 90–100°C. After their dry weight had been recorded, the samples were ground to powder, and a weighed portion was extracted with petroleum ether to remove neutral fat and lipids and then reweighed. The remaining fat-free dry solids (F.F.D.S.) were then extracted in an appropriate volume depending on the weight of the sample and on the sensitivity of the methods (usually 2–5 ml.) of 0.1N H_2SO_4. Cl was estimated after 3–5 days' extraction either by the 'fast green" microdiffusion method (Gordon 1952) or by amperometric titration with a dropping Hg calomel electrode system with 0.02N $HgNO_3$ (Kolthoff and Miller 1941). Na and K were estimated in appropriate dilution with a single-ended Zeiss flame photometer using interference filters. Calculations were based on the Cl assumption as applied by Darrow and outlined in numerous sources (Cort 1955). All the calculations are in terms of m.eq. or ml. per 100 g. of F.F.D.S., and all the serum levels are in m.eq. per litre.

Results

The results are summarised in the accompanying figure. The physiologically important results from each group are averaged. In view of the difficulties always encountered in selecting such groups, particularly of different ages and with different dietary histories, it is surprising to find such significant differences in intracellular K and Na. Intracellular water showed smaller changes than did Na.

Effects of Pregnancy Alone.—Skeletal muscle tended to contain less intracellular K and slightly more intracellular Na in pregnancy. Its extracellular composition, however, remained normal. The myometrium showed statistically significant changes, a loss of K and a sharp gain of intracellular Na and water. The increased amounts of extracellular Na, Cl, and water in the uterine samples presumably reflects merely the increased blood volume of the pregnant uterus.



Results of electrolyte analyses.

Effects of Normal Labour.—At this period of pregnancy, an average of 2–3 weeks later than in the previous group, there was a greater tendency to a generalised K deficiency, with a further loss of muscle K and gain of Na. The greatest extra-uterine changes during labour were the development, in most of the patients, of extracellular metabolic acidosis (high Cl, low HCO_3) and dehydration (higher serum-Na level, lower muscle-water values). Myometrium, in common with skeletal muscle, showed a further loss of K and gain of Na and water in cells. "Total base," estimated by the sum of Na and K, also increased in cells. The relative diminution of extracellular space in the myometrium, compared with the pre-labour gravid uterus, may be the result of cellular swelling or of muscular contraction.

Effects of Prolonged Ineffective Labour.—As might be expected, this group showed the most extreme changes of all, both in uterine and skeletal muscle. Skeletal muscle showed a clear picture of mild or moderate K deficiency, reflected by a tendency to hyponatræmia, hypochloræmia, and a high extracellular Cl : HCO_3 ratio (Cort and Matthews 1954, Cort 1955). Myometrium showed an even greater loss of K, with a gain of Na, water, and "total base," which resembled in degree what happens to tissues when the active transport of Na is blocked by cold, anoxia, enzyme poisons, &c. (Davies 1954, Cort and Kleinzeller 1956). Because of the design of the experiment, it was impossible to obtain the dietary history of the patients throughout pregnancy and to make rough balance studies to ascertain K balance. The incidence of prolonged ineffective labour did not correlate with either Hb level or hæmatocrit during pregnancy or with the rate of weight gain (toxæmia had been excluded from this series).

Discussion and Conclusions

It seems that the increased opportunities of losing potassium during pregnancy (fœtal and perhaps urinary losses) may cause a deficiency of potassium by the end of pregnancy, and that this deficiency is not evenly distributed, being more pronounced in the myometrium than in skeletal muscle. From the purely obstetric point of view this loss of potassium might be expected to prejudice the ability of the myometrium to contract, and it suggests that, in the women investigated, the intake of potassium was insufficient during pregnancy. The general stress and intense myometrial activity during labour could be expected to exaggerate the loss of potassium at the end of pregnancy. Moreover metabolic extracellular acidosis was also present in nearly all the patients during this period, a factor which per se can lead to a loss of cell K Anoxia and the production of adrenal hormones during labour may also change the electrolyte pattern in the myometrium Intracellular K is associated with glycogen, and West and Cervoni (1955) have shown (in the rat) that œstrogens increase the amount of glycogen in the myometrium, whereas uterine contractions and anoxia decrease it Biopsy specimens in the present investigation were seldom large enough to permit glycogen analysis as well as electrolyte analysis, but it might well be that changes in uterine glycogen would parallel those in uterine K

It is impossible to say whether the changed electrolyte pattern found in the myometrium of patients with prolonged ineffective labour was a cause or a result of the abnormal labour We rather think that it is both The intracellular hyponatræmia and overhydration of the myometrium suggest that local anoxia, affecting the transport of Na, may also be present If this is true, the calculations would contain a greater error than is usually attributed to the Cl assumption It is furthermore not known how well the Cl space calculation agrees with other extracellular-fluid markers in the myometrium, but the changes in intracellular K and Na recorded here are sufficiently significant to render it doubtful whether error associated with any extracellular-fluid marker would negate the changes found

Our results are, of course, preliminary, and further work will be required to elucidate the mechanisms involved in these changes and the possible clinical application It would probably be useful to repeat the investigation in animals under more controlled conditions and to investigate further the possible occurrence of K deficiency in pregnancy and the possibility of treating prolonged ineffective labour by the rapid deposition of K in the cells, by for example, infusion of glucose, K, and insulin

Summary

Biopsy specimens from uterine and skeletal muscle were analysed from the following groups of patients non-pregnant, in the third trimester of pregnancy before the onset of labour, during active labour, and during prolonged ineffective labour

All the samples were taken during uterine surgery for other reasons

Pregnancy per se was associated with a significant loss of myometrial K and a gain in cell Na, water, and total base in the uterus There were slight changes in the same direction in skeletal muscle (rectus abdominis)

Normal labour caused a loss of K and a gain of Na, water, and total base in myometrium

Prolonged ineffective labour was associated with the most severe changes of the above type in the myometrium, and was also associated with clear signs of K deficiency in skeletal muscle and in the extracellular fluid

Normal labour often produced a metabolic acidosis

We wish to thank Mr M Noble, F R C S E, for initially suggesting the importance of this study, and Dr S Franz and Dr L Vojta for their kindness in permitting us to investigate their patients and for assisting in the investigations Particular thanks are due to Miss D Rosicka for invaluable technical assistance

LEPTOSPIROSIS IN ENGLAND DUE TO FOREIGN SPECIES

E E F KEAL
M B Lond, D C H
MEDICAL REGISTRAR, ST JAMES' HOSPITAL, BALHAM, LONDON

Broom stated in 1951 that all cases of leptospirosis then recognised in this country had been due to *Leptospira icterohæmorrhagiæ* or *L canicola* He further investigated the sera from 642 cases of aseptic meningitis in which viral infection had been excluded and found 17 cases of Weil's disease and 8 of canicola fever but no evidence of infection with "foreign" leptospiræ, of which *L bataviæ*, *L grippotyphosa*, *L pomona*, and *L sejroe* were chosen as a representative series Since that time the Wellcome Research Institute has acted as the Leptospira Reference Laboratory for the Public Health Service covering England and Wales, and Broom (personal communication) states that none of the "foreign" species has been identified as the causal organism of disease in this country until the present case

Case-report

A Malayan engineer, aged 32, left Malaya by air on Sept 3, 1955, and arrived in this country the following day During the previous 6 months he had worked on the foundations of a new bridge at Ulu Selangor, a swampy region of Central Malaya He was admitted to this hospital on Sept 20 with 7 days' history of malaise, anorexia, and absolute constipation He had had occasional slight headaches but no muscle or joint pains and no photophobia He had not noticed any reduction in the volume of his urine but said that it had been dark

On admission his temperature was 103°F, pulse rate 104, and respirations 20 a minute He had moderate conjunctival suffusion, no anæmia or jaundice, no glandular enlargement blood-pressure 140/95 mm Hg Heart sounds normal, no murmurs Chest clear Liver impalpable but spleen enlarged two finger breadths below the costal margin, firm, and not tender No neck rigidity Kernig's sign negative No other abnormality in the central nervous system

Investigations —Hb 94% (13 9 g per 100 ml), white cells 17,300 per c mm (neutrophil polymorphs 80%, lymphocytes 14%, monocytes 6%), no malarial parasites, blood culture negative, urine contained albumin, occasional red cells and leucocytes, and amorphous debris, no organisms seen and sterile on culture Widal test positive to a titre of 1 in 160 for *Salmonella typhi* and *S paratyphi-A* H agglutinins and to 1 in 80 for *S paratyphi B* H agglutinins It was negative at all dilutions for O agglutinins and for *Brucella abortus* and *Br melitensis* These results were compatible with the patient's T A B vaccination a month before leaving Malaya The Wassermann reaction of the blood was negative Liver function tests thymol turbidity 10 units, thymol flocculation +++, Takata Ara reaction ++, van den Bergh negative direct and indirect, serum bilirubin level 0 4 mg per 100 ml, serum alkaline phosphatase level 7 4 units No ova, cysts or parasites were seen in the stools, and no pathogenic organisms grew on culture Dr Broom, at the Wellcome Research Institute, made leptospira agglutination tests and reported that the patient's serum agglutinated *L grippotyphosa* to a dilution of 1/3000, *L icterohæmorrhagiæ* to 1/300, and *L canicola* to 1/300 there was no agglutination of *L bataviæ* or of *L sejroe* When the tests were repeated 10 days later, agglutination of *L grippotyphosa* was maintained at a titre of 1/3000, whereas the others had fallen to 1/30 These results established the diagnosis of leptospirosis due to *L grippotyphosa*, a serotype endogenous in Europe and Asia and carried by the field mole

Progress —Clinically the infection was mild, with none of the severe muscle and joint pains and meningeal or renal symptoms sometimes seen in this disease The patient felt well after a few days, though pyrexia persisted for a further 12 days—i e, 19 days from the onset of symptoms Liver function tests 2 months after the onset were thymol turbidity 7 units, thymol flocculation ++, Takata Ara reaction +, serum bilirubin level 0 6 mg per 100 ml, serum alkaline phosphatase level 6 4 units

Comments

Leptospirosis is relatively common among British troops in Malaya: 160 confirmed cases in 1954 and more than 200 in 1955 The incubation period is usually given as 4–12 days (not less than 10 in the present case) and with the increasing use of air transport it is surprising that more cases due to foreign species have not occurred in this country This, and an equally surprising low reported incidence of canicola fever in view of the 30–40% infection-rate among dogs in this country, are probably explained by the benign and self-limiting nature of leptospirosis and a consequent reluctance to pursue difficult and prolonged investigations Thus leptospirosis was not specifically excluded in 113 cases of "pyrexia of unknown origin" reported by Reid (1956), though 41 remained undiagnosed. Alston and Broom (1949) drew attention to the resemblance of the meningeal form to non-paralytic poliomyelitis, and Ramsay (1955) reported 4 such cases of canicola fever where the presence of mild conjunctivitis and nephritis prompted further investigation.

Summary

All cases of leptospirosis previously reported in this country have been due to either *L icterohæmorrhagiæ* or *L canicola*

A case due to a foreign species, *L. grippotyphosa*, is described

It is again suggested that the true incidence may be greater than that reported

I thank Dr. Alexander Kahan for permission to publish and Dr J C Broom for the agglutination tests.

FAILURE OF PROPHYLACTIC ORAL PENICILLIN TO INHIBIT A HUMAN LABORATORY CASE OF LEPTOSPIROSIS

J C Broom
O.B.E , M D St And.
BACTERIOLOGIST, WELLCOME LABORATORIES OF TROPICAL MEDICINE, LONDON

T St.M. Norris
M.A , M.D Camb , M.R C.P
CONSULTING PHYSICIAN, WHITTINGTON HOSPITAL, LONDON

THIS case seems worth reporting because of the unusual mode of infection and also because of the failure of a prophylactic course of penicillin to prevent the disease

The strain involved (R 43676) was isolated in Malaya from *Rattus rattus argentiventer* It belongs to the *javanica* serogroup, but its serological reactions are not identical with those of either *Leptospira javanica* or *L poi* (the two members of the group already known) The accidental infection took place during the preparation of a homologous antiserum for further investigation of the antigenic constitution of the strain

Case-report

The patient, a man aged 50 is a chief laboratory technician with many years experience of handling cultures of leptospires. On Oct 18 1956 a syringe containing 10 ml of living culture slipped from his hand as he was on the point of inoculating a rabbit In an attempt to prevent the syringe from being shattered on the floor and disseminating the culture widely he put out his foot to try to break its fall. The syringe must have dropped almost vertically point downwards for the needle passed through the leather upper of his shoe and penetrated his foot The needle snapped off at the mount so only a very small quantity of culture could have been injected (Incidentally, the syringe did not break.)

The Illness

A small and slightly lacerated wound was found on the dorsum of the foot and was immediately swabbed with spirit. As a prophylactic measure it was decided to give penicillin by mouth, and the first dose, 1,000,000 units, was administered within an hour of the accident Thereafter penicillin 500,000 units was taken 6-hourly to a total dosage of 6,000,000 units. The wound healed by first intention, but on the 8th day after the accident it became red and sore with puffiness of two toes, though there was no general disturbance On the 9th day the patient had flatulent indigestion, relieved by sodium bicarbonate, and on the 10th day he felt feverish and had severe headache In view of the history he was admitted to hospital on the same day

On admission his temperature was 99°F and pulse-rate 88 He was a fit-looking man with a slightly furred tongue but with no conjunctival injection, neck stiffness, or glandular enlargement There was a tender area of erythema about ½ in. in diameter on the dorsum of the left foot but no abnormal physical signs were found anywhere else The liver and spleen were not palpable, Kernig's sign was negative, and the urine contained no albumin

Next day he complained of severe general malaise with headache and pain behind the eyes. His temperature rapidly rose to 103°F and his pulse-rate to 105 Neck stiffness was present He was immediately treated with oxytetracycline 250 mg 6-hourly for five days His malaise and temperature persisted for 72 hours, after which his general condition rapidly improved, and his temperature returned to normal At no stage was there any diminished secretion of urine

Laboratory Investigations

A blood-culture in glucose broth gave no growth after 6 days The blood-urea level was 21 mg per 100 ml, hæmoglobin 102% and leucocytes 6750 per c mm (differential count normal) Lumbar puncture on the 3rd day produced clear cerebrospinal fluid under a pressure of 90 mm. water, with a free rise to 140 mm on Queckenstedt's test, and containing 1 cell per c.mm. protein 15 mg per 100 ml., and sugar 67 mg per 100 ml. The urine showed no abnormality Tests for bile salts and bilirubin were negative Urobilinogen was present in normal amounts

Two samples of venous blood were taken on the 1st day of illness and one was injected into a guineapig and a golden hamster intraperitoneally Next day blood-cultures were made in Korthof's medium from the second sample, and serum was removed for agglutination tests. Leptospires were seen in the blood-culture after incubation for 7 days The remainder of the blood was treated by the method of double centrifugation described by Ruys (1933), and a few motile leptospires were seen microscopically in the final sediment

Four days after the animals were inoculated numerous leptospires were visible in the peritoneal fluid of the hamster but not in that of the guineapig The hamster was killed next day, and the strain was cultured from the heart blood. The guineapig never showed signs of infection either during life or at necropsy 3 weeks later

The serum taken on the day of onset contained no agglutinins for strain R 43676 A sample obtained on the 12th day of illness agglutinated strain R 43676 to a titre of 1/3000, and a specimen taken about 10 weeks later to 1/1000

Comment

Although a short incubation period has been reported in some laboratory infections of leptospirosis, the period of 10 days in this case is within the usual range There is thus no indication that the administration of penicillin even delayed the onset. There is ample evidence from experiments on animals that a course of penicillin begun soon after infection. prevents the development of the disease. Failure in the present instance may have been the result of too small a dosage, too short a course, or a combination of the two factors

The clinical picture differed from that seen in either classical Weil's disease or infection with *L canicola* in that there was no evidence of either renal or hepatic involvement There was no meningitis and no conjunctival injection The appearance was that of an acute uncomplicated septicæmia

Treatment with oxytetracycline may or may not have modified the course of the illness.

Summary

A laboratory worker contracted leptospirosis from an accident in which the needle attached to a syringe containing live culture pierced his shoe and penetrated his foot

Oral penicillin to a total dosage of 6,000,000 units in 3 days did not prevent the onset of leptospirosis

The infecting strain was obtained in culture from the blood and indirectly by inoculating a golden hamster

The clinical picture suggested acute septicæmia rather than leptospirosis

Treatment with oxytetracycline may or may not have modified the course of the illness

Reviews of Books

The Gist of Obstetrics

H B ATLEE, M D, F R C S, F I C S, head of the department of obstetrics and gynæcology, Dalhousie University, Halifax, Nova Scotia, Canada Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 327 45s

THIS is something quite different The author has given up systematic lectures to undergraduates, and his book has developed from a set of notes which he hands out to his students The title is appropriate, because details have been kept to a minimum and the style is more like that of a novel than of a textbook On the important principles of obstetrics, instruction is clear and dogmatic and often phrased in such a way that the student is unlikely to forget it The book is essentially practical and the line drawings are clear and self-explanatory The student should not rely on it as his only book of reference—it is not intended as such—but both he and the practitioner will find it a very useful practical guide and they will enjoy reading it Teachers will find in it many expressive phrases that they can borrow The bleeding of placenta prævia is " quiet and sneaky " Of transverse lie, " the disasters arising out of this presentation can all be avoided by early diagnosis It is when the baby's little hand has come through the vulva to wave at you that you are friendless in Gaza "

Essentials of Physiology by Bainbridge and Menzies

10th ed Edited and revised by H HARTRIDGE, M A, M D, SC D, M R C P, F R S, emeritus professor of physiology, University of London, J L D'SILVA, M B, PH D, D SC, M R C P, professor of physiology in the University of London at the London Hospital Medical College London Longmans, Green 1957 Pp 506 36s

THERE has been no new edition of this work since 1940 Owing to changes in these sixteen years the book has had to be vigorously revised and largely rewritten The editors have done remarkedly well to cover the essentials in a bare 500 pages Inevitably the subject is treated dogmatically, but, as the editors state, their aim was to write a book for the ordinary medical student—that is, one who will attend lectures and practical classes where the variations and uncertainties of biological work will be pointed out The student will be glad to have this book for summarising and revising the subject The writing is clear and straightforward, and many of the illustrations are new

The Dramatic Universe

Vol I *The Foundations of Natural Philosophy* J G BENNETT London Hodder & Stoughton 1957 Pp 534 42s

THE author's intention is to " explain the universe "—a task rejected as unprofitable by many modern philosophers—and he shows great learning and ingenuity Since it has so far seemed impossible to elucidate a mechanical structure of the world and all that therein is which satisfies not only observation but common sense he proposes, instead of the usual dualist solution of the problem, a schema based upon a fifth dimension of " eternity " Unfortunately, though he sees the whole domain of forest far clearer than most of us, he labels the individual trees with names not commonly in popular or scientific use This has been a difficulty with many a cosmogonist, and arises from the poverty of dead and living languages · he must either coin new names or pay old ones extra and make them mean what he likes Even the glossary might be more helpful to the novice—for example, " Corpuscle The bipotent state of hyle Compromises electrons, positrons, photons, neutrinos and mu-mesons " Inevitably, perhaps, a great deal of the book is hard to follow, but the subject is a suitable one for study by the thoughtful and inquisitive

Analytical Pathology

Treatises in the Perspective of Biology, Chemistry, and Physics Edited by ROBERT C MELLORS, M D, PH D, assistant professor of pathology, Cornell University Medical College, Sloan Kettering Division, New York New York, Toronto, London McGraw Hill 1957 Pp 477 90s

THIS curious subtitle seems to mean that these eight essays, or surveys, dealing with pathological subjects are concerned to show how biochemistry and some biophysics can be correlated with morbid anatomy, experimental pathology, and even therapy When the reader ventures beyond this discouraging title, he will find the essays rewarding, they are relatively short and contain a remarkable amount of information Some of the chapters are simply reviews—with all the dullness of style that we have come to expect in this sort of article But others are readable and intelligent syntheses

The chapter on the biology, biochemistry, and pathology of cancer by the editor is one of the best, and the chapter on macrocytic anæmia by John F Mueller and Richard W Vilter is also particularly well done, it starts with a discussion about nucleotides and how folic acid and vitamin B_{12} are concerned with their metabolism, and progresses via some mention of megaloblasts to the actual treatment of the anæmias The chapter on the adenohypophysis by Agnes B Russell deals with recent histochemistry as well as with experimental work in animals

The other surveys are on arteriosclerosis and hypertension by John W Gofman, inflammatory and vascular diseases of the glomerulus by David B Jones cholæmia, ascites, and hæmorrhagic phenomena in liver failure by Oscar B Ratnoff, abnormal hæmoglobins by John J Will, and the rôle of connective tissue in hypersensitivity by Bernard M Wagner All have their good points, and workers in the particular fields will be sure to find some original way of looking at and putting together the material available Each chapter has a summary or a paragraph setting out its conclusions, and most of them have an extensive bibliography

Handbuch der Orthopädie

Vol I *Allgemeine Orthopädie* Edited by Prof Dr G HOHMANN, Munich, Prof Dr M HACKENBROCH, Cologne, Prof Dr K LINDEMANN Heidelberg Stuttgart Georg Thieme 1957 Pp 1186 D M 178

THIS beautifully produced book is the work of its editors and some 20 co-authors It is the first of four volumes which are designed to replace the classic German " handbook " of Joachimsthal, now past its fiftieth birthday Nothing comparable has been produced in Germany since then, and with the vast increase in knowledge during this century the demand for such an edition cannot be doubted

It contains a series of up to-date essays surveying in general terms the whole of orthopædics including long chapters on physiotherapy British readers will note with interest the stress laid on the logical inclusion of trauma in the orthopædic field, in Europe opinion has not advanced so far down this road as in Britain or America Discussion of treatment has been reserved for later volumes, which makes for heavy reading in the first but does not detract from its high quality

---

Contemporary Rheumatology (Amsterdam Elsevier London Cleaver Hume 1956 Pp 654 95s)—The proceedings of the European Rheumatology Congress held in Holland in 1955 have been published under the editorship of Prof J Goslings and Dr H van Swaay.

THE LANCET

LONDON SATURDAY, APRIL 6, 1957

The Staphylococcus Plague

REGULAR readers of medical journals seldom have to wait long for an account of some more or less grave episode of staphylococcus cross-infection in a hospital The latest instance in our own columns was last week's report by Dr GRESHAM and Dr GLEESON-WHITE of staphylococcal bronchopneumonia Of course there has always been staphylococcal cross-infection in hospital, and the nasal-carrier rate has always been greater in hospital staff than in the general population, but this discrepancy has increased dramatically in recent years Bacteriologists with fewer hæmolytic-streptococcal epidemics to investigate, now have more time for staphylococci, and a growing number of bacteriologists have profited from the invaluable work on phage-typing at Colindale But unfortunately, there is no reason to believe that the problem of staphylococcal cross-infection in hospital is being artificially inflated by these factors We face, indeed, a hospital plague It is properly the duty of a hospital authority to maintain a clean and wholesome sick-house and many hospital authorities would probably be bewildered at suggestions that they may be failing in this respect Yet they are In olden days people were afraid to enter plague-houses Nowadays, if they knew all the facts, they might justifiably hesitate to run the risk of being operated on or delivered within even pleasant-looking hospitals, for these, no less than the obviously unattractive ones, may at any time be stricken by an outbreak of our modern plague—virulent staphylococcal cross-infection

It is hard to see an easy, early, or complete remedy, but there is much that should be done, and some of it is fairly obvious and far from difficult if we abandon some of our thoughtless habits We should clearly begin with a ruthless examination of our use of antibiotics When these drugs were introduced the fear was expressed that general practitioners would misuse them and thus spoil their efficacy by fostering resistant bacteria and sensitising patients Ironically, whatever general practitioners may have done in this respect, the effects of misuse are clearest in hospitals The trouble is not, as was feared, that insufficient therapy leads to the emergence of resistant variants of a sensitive strain of staphylococcus in the individual patient, but that antibiotic-resistant staphylococci prevail in the hospital population—attendants as well as patients In hospitals uncritical use of antibiotics for every imagined reason, and for none at all, has so led to the replacement of sensitive staphylococci by naturally resistant and apparently hardier strains which are normal inhabitants of the nose—even of people who have never been treated with an antibiotic This is the heart of the problem

Individual hospital clinicians practise restraint in prescribing antibiotics, but their wise conduct may have disappointingly little effect unless all the staff of a unit—indeed perhaps all the staff of a hospital—adopt the same policy. The surest way of ensuring agreed action is by regular meetings of a cross-infection committee in each hospital We need to notify each one of these infections to a responsible centre of information in the hospital, to study the bacteriology and epidemiology of each episode, and to discuss whether and how further episodes may be prevented In some hospitals—too few by far—cross-infection committees do useful work in this way and even act as a forum at which a policy for the use and non-use of antibiotics may be worked out Such a committee also has a notable educative value For example, some hospital doctors (including many of the residents, who often do much of the prescribing) are probably unaware of the harm that may be done by some of the antibiotics and antibiotic combinations that have recently been introduced—to the dismay, it may be said, of the more responsible advisers of the drug firms themselves There is no justification for giving penicillin and streptomycin together almost as a routine This powerful combination should be used only with good reason—for example in resistant forms of endocarditis In many hospitals, thanks to intelligent and planned restraint, it is still impossible to isolate an erythromycin-resistant staphylococcus In such hospitals an acute life-endangering staphylococcal infection may confidently be treated, without waiting for sensitivity tests, with erythromycin, and it is with this object that some hospital staffs have voluntarily restricted their use of this valuable drug This limitation is hard on the manufacturers of erythromycin, as we have said before, and there may be a case for compensating firms which produce an antibiotic too valuable for general abuse But it is harder still for such firms to see appearing on the market drugs that have few if any virtues peculiar to themselves and will assuredly do harm if they are used widely enough to produce cross resistance to erythromycin This criticism does not apply to such genuinely new antibiotics as novobiocin and vancomycin.

Restraint in the use of antibiotics is not our only weapon against the plague of staphylococcal and of other cross-infections We cannot afford universal air-conditioning in hospitals, but every surgical unit should have an air-conditioned room for its wound dressings (it is certainly no longer possible to find a word to say for the practice of dressing open wounds in general wards) We need to get rid of operating-theatre suites whose air-flow comes from the wards and corridors, or from the anæsthetic room or sterilising-room into the theatre itself, we need to deal with 'sterilisers" that do not sterilise or that may—because of absent or deficient air-filters—contaminate after sterilisation We need to be sure that wards and operating-theatres have a decent flow of fresh air even if it is not fully controlled and conditioned, for there are many wards and theatres in which the atmosphere of still over-heated air may favour cross infection We need to find acceptable ways of sterilising blankets regularly or to devise new kinds of blankets that can be sterilised by steam By such methods, but above all by constant awareness of the risk of cross-infection and determination not to abuse antibiotics, we can surely begin to lift this modern plague from our hospitals

Cæsarean Section

CÆSAREAN section may be preferred as a seemingly easy alternative to vaginal delivery (though for different reasons) by both obstetrician and patient Yet the maternal mortality for this operation is still about ten times greater than that for vaginal delivery, and in Brooklyn, New York, in 1937–50 cæsarean section was a constant factor in about 20% of all puerperal deaths[1] The features which have contributed to the progressive decrease in maternal morbidity and mortality from cæsarean section—including the use of blood-transfusion, antibiotics, and ergometrine—have also reduced the risk of vaginal delivery D'ESOPO[2] reported that complications of cæsarean section in 1000 cases at the Sloane Hospital, New York, included the following puerperal infection, 107, wound infection, 29, surgical shock, 27, thrombo-embolic disease, 24, burst abdomen, 2, intestinal obstruction, 2, damaged bladder, 1, hæmorrhage requiring hysterectomy, 1 MARSHALL and COX[3] reported that of 7762 cæsarean sections in nineteen British teaching hospitals during 1943–47 the maternal mortality was 0 99% Such figures are a corrective to the view that cæsarean section is preferable to any obstetric operation other than the simplest type of low forceps and that all other methods of delivery will become obsolete[4 5]

The classical cæsarean section, which has many disadvantages, has been largely replaced by the lower-segment operation In the classical approach the fœtus is extracted feet first and commonly takes deep inspiratory gasps before delivery is complete, liquor amnii is thus aspirated into the respiratory passages and fatal atelectasis may result The incision, in the anterior uterine wall, is subjected to intermittent tension with each "after-contraction" of the puerperium This leads to the formation of a gutter on the under-surface of the scar which may be the starting-point of rupture in a subsequent pregnancy[6] The uterine scar is exposed to the peritoneal cavity, and gut may become adherent and later strangulate Nevertheless the occasional surgeon working under emergency conditions finds this the easier operation, and for his patient it may be the safer WATERS[7] advocated an extraperitoneal approach, to reduce the risk of disseminating intra uterine infection, but the operation is difficult, and has been abandoned in this country Occasionally the bladder is damaged, commonly the peritoneum is opened, and the incidence of serious infection is not reduced

Many of the difficulties and dangers of the lower-segment operation can be avoided by careful attention to technique[8]

The bladder is kept empty by an indwelling rubber catheter The peritoneum over the lower segment is incised transversely near the upper limit of its loose attachment, and the bladder is pushed down by very gentle finger separation A midline catgut traction-suture is inserted in the lower segment, which is incised progressively with a scalpel while the muscle is pulled away from the fœtal head When the amniotic sac is opened the incision is completed by separating the transverse fibres with digital stretching With a finger in the infant's mouth the head is rotated occiput posterior, the chin is hooked out over the upper uterine flap, and the head is delivered slowly by flexion with the hand A head impacted in the pelvic brim can be freed by mild Trendelenburg tilt Intravenous ergometrine 1 0 mg is given and spontaneous expulsion of the placenta is awaited Meanwhile lateral traction sutures are placed in the lower segment incision Commonly the placenta is delivered by cord traction, but in cases where the uterus is atonic this results in profuse hæmorrhage from the placental site Continuous sutures in the lower segment may cause severe ischæmia and the formation of a weak scar, interrupted sutures of fine catgut are preferable Aspiration of blood and liquor which have spilled into the peritoneal cavity will reduce the incidence of postoperative distension of the bowel Intravenous fluids are not given as a routine, but where much blood-loss is expected, as in placenta prævia, an intravenous drip should be set up before operation Prophylactic antibiotics are administered where sepsis is expected—particularly after prolonged labour with ruptured membranes

The risk of ruptured uterus after cæsarean section is increased by each subsequent pregnancy and vaginal delivery, by high parity, by multiple pregnancy, large fœtus, and hydramnios, and by implantation of the placenta beneath the scar[9] In many clinics in the U S A a cæsarean-section scar is regarded as an absolute indication for terminating further pregnancies in this way, and in 1954 in Brooklyn 38 7% of cæsarean sections were done for this reason[10] This will not completely eliminate the risk of scar rupture, since 25% of ruptures following the lower-segment operation and 50% of ruptures following the classical operation take place before the onset of labour

Rupture of the classical scar is more dangerous to both mother and child DEWHURST[11] reports that in 762 pregnancies of women who had undergone the classical operation the scar ruptured in 17 cases (2 2%) In 100 reported cases where the scar ruptured, the maternal mortality was 5% and the fœtal mortality 73% In 40% of all cases the placenta overlies the scar After rupture the uterus contracts and retracts, the amniotic sac ruptures, and often the placenta and fœtus are partly expelled into the peritoneal cavity, hæmorrhage from the placental site is profuse, and the patient presents the picture of severe shock She has severe continuous abdominal pain and tenderness, the fœtal heart cannot be heard and the fœtal parts may be easily felt Intermittent labour pains usually cease, and there may be slight vaginal bleeding The fœtus dies from cord compression, placental separation, and maternal cardiovascular collapse

Rupture of the lower-segment scar is less dangerous and less usual DEWHURST[11] reports 8 cases in 1530 pregnancies (0 5%) Rupture may be gradual and unaccompanied by dramatic symptoms Even where symptoms and signs are more pronounced and the peritoneum is involved, the fœtus is usually—but not always[12]—retained in utero, the placenta is rarely involved, and bleeding is usually slight The fœtal loss is consequently less (12 5%) and in this country no maternal death has been recorded In the presence of a lower segment scar, therefore, the mode of delivery will depend largely on the indication for the first cæsarean section If this was on account of a recurring cause, such as contracted pelvis or diabetes mellitus, an elective lower-segment cæsarean section is indicated Otherwise vaginal delivery, carefully supervised in hospital, with facilities for immediate transfusion and operation, is to be preferred The second stage of labour should not exceed fifteen minutes, and if necessary,

very is hastened by episiotomy and forceps It is e to palpate the lower segment with two fingers to clude late rupture during fœtal expulsion

uspected rupture of the scar is best treated by esuscitation and immediate laparotomy—especially f labour is established After delivery of the fœtus and placenta, either the uterus is repaired and the fallopian tubes ligated, or, in the more severe case, subtotal hysterectomy is undertaken

Half the fœtal deaths in deliveries by cæsarean section are attributable to the risks inherent in the operation itself In Brooklyn in 1954 there were 2693 cæsarean sections 2714 infants were delivered with 44 stillbirths and 90 neonatal deaths—a perinatal mortality-rate of 49 4 per 1000 live and still births, which represents an incidence about 55% above the general perinatal mortality for New York city (GORDON[10]) We should therefore hesitate before deciding on cæsarean section solely in the interests of the infant

Progress in Argentaffinomatosis

ARGENTAFFINOMATOSIS—the syndrome resulting from the secretion of 5 hydroxytryptamine by argentaffinomas—is now familiar, though rare In cases of obscure cyanosis or flushing and in pulmonary stenosis, it is accepted that abdominal carcinoids come into the differential diagnosis, and the estimation of urinary 5-hydroxy-indole acetic acid is established as a valuable diagnostic measure[1 2] But of the underlying biochemistry and physiology of the process much remains to be learnt

One of the most interesting aspects concerns the source of the 5-hydroxytryptamine (5-H T) Metabolic studies on relatively large series of patients in Bethesda[3] and Glasgow,[4] supported by the use of isotope-labelled tryptophan,[3] have shown very clearly that the 5 H T is derived from tryptophan In some cases a very large proportion of the normal dietary intake of tryptophan is diverted to this process, and this, combined with the diarrhœa often present, leads to a considerable risk of a nicotinic acid/tryptophan deficiency[4] The conversion of tryptophan to 5 H T seems simple enough Oxidation of tryptophan at C 5 produces 5-hydroxytryptophan, and loss of CO_2 from the carboxyl group produces the corresponding amine, 5-H T GADDUM and GIARMAN[5] demonstrated the presence of a decarboxylase which accomplished the second part of this process and showed that its distribution corresponded fairly well with the sites of formation of 5-H T The first part remains elusive The tryptophan oxidase that would produce 5-hydroxytryptophan has never yet been demonstrated in animal tissues Tryptophan incubated with rat liver slices, for instance, undergoes no 5 hydroxylation One of the cases in the Glasgow series[4] was therefore of especial interest, for 5 hydroxytryptophan in substantial quantities appeared in the urine, apparently from renal metastases of the tumour This is valuable confirmation of the reality of the postulated route of formation DALGLIESH and DUTTON go further, and deduce that the tumour, and so presumably the normal argentaffin cells from which the tumour has arisen, must be capable of this essential 5-hydroxylation of tryptophan SJOERDSMA et al[3] failed to demonstrate such an action in tumour tissue, but so fruitful is this hypothesis that their findings should be re-examined It follows if DALGLIESH and DUTTON are right, that the major function of the argentaffin cells is not the local release of 5-H T (though this may be one of their functions) but the manufacture of its precursor, 5-hydroxytryptophan, for circulation to various other cells which decarboxylate it and turn it into the active hormone Among other things, this would account for the fact that though 5 H T is produced apparently by several different kinds of cells, no other kind of tumour produces excess of it The body's total production of 5-H T is presumably limited by the availability of the precursor, and only the argentaffinoma can produce excess of the precursor The elimination of 5-H T by oxidation to 5-hydroxy-indole acetic acid (5-H I A A) is effected by an amine oxidase present especially in the lungs MACFARLANE et al[2] made the interesting suggestion that some of the discrepancies between the intensity of symptoms and the level of hormone production (one of their patients excreted 600 mg of 5-H I A A a day but had no relevant symptoms except slight diarrhœa) might be accounted for by an adaptive rise in the amine-oxidase content of the lungs But this possibility has been eliminated by DAVISON and SANDLER,[7] who showed that the lung amine-oxidase remains at normal levels The relation to 5-H T. secretion of the most striking feature of the syndrome—the vasomotor changes which account for the flushing and cyanosis—is uncertain[4]

Nothing further seems to have been learnt of the origin of the endocardial lesions Their constant appearance downstream from the main tumour masses makes it difficult to believe that we are not seeing a direct effect on the endocardium of some toxic material produced by the tumour But what[2] 5-H T seems the only possible answer, yet no action of 5-H T that would account for its damaging the endocardium is known Its presence in high content in the platelets does not seem to damage them, and there is no evidence from the few adequate post-mortem studies reported[8-10] that platelet deposition or thrombosis play any part One can only assume that 5 H T in high concentration has some unrecognised action on the endocardium, or that some unrecognised secretion of the tumours is the culprit Even that most satisfactory observation of GOBLE et al[11]—namely, a substantial removal of 5-H T from the blood during its passage through the lungs in one patient (thus accounting, it seemed for the difference between the lesions in the left and right hearts)—has been challenged by SJOERDSMA et al,[3] who found no difference between the 5-H T content of pulmonary-artery blood and femoral-artery blood Among confusing observations it is a relief to find in the Glasgow series studies of gastric function (high pepsin

and low acid) and of renal function (inconstant oliguria) with results that fulfil physiological prediction. The increased production of 5-H T in response to reserpine is also not unexpected, but the failure of 5-H T antagonists to influence the syndrome is hard to account for. It is especially disappointing to find a failure to confirm Bleehen's[12] report of an alimentary stimulus to 5-H T secretion, in which we once[13] thought we saw evidence of an intermediary hormonal mechanism.

This syndrome is only one of the many aspects of the biochemistry and pharmacology of the aromatic amino acids in which, largely under the influence of chromatographic methods,[14] rapid advances are being made. Two recent studies remind us that the aromatic amino acids and their derivatives should not always be considered separately: first, the description by Waldenström et al.[15] of an argentaffinoma which appears to secrete large amounts of histamine as well as 5-H T, and second, the demonstration that 5-H T metabolism is involved in phenylketonuria.[16] We might also note the claim of Boyland and Williams[17] that some normal urinary indole derivatives may be carcinogenic for the bladder.

THE BOMB TESTS

On his return from Bermuda, the Prime Minister declared that the forthcoming tests of thermonuclear weapons at Christmas Island in the Pacific would be "so small and on such a restricted scale that they cannot really add to anything that would be dangerous to the world"[1], and on Monday he said he was satisfied that the radiation effects would be insignificant. The most likely interpretation of "small" is that the bombs will contain only a lithium-deuterium mixture detonated by an "ordinary" atomic bomb, and that the mass of uranium which gave earlier hydrogen bombs their enormous power, and which was responsible for most of the radioactive contamination they caused and are still causing, will be omitted or much reduced. If that is in fact what is planned, the new tests will generate much less radioactivity than previous thermonuclear explosions, and immediate fears about their consequences will be eased.

Small "clean" bombs may have been the Government's intention all the time, and the outcry at home and abroad against the tests may have forced it to disclose what they hoped to keep secret. On the other hand, a small explosion would be something of an anticlimax: one of the main reasons for having the tests (and it is a reason which, in the Government's view, may outweigh potential dangers) is presumably to demonstrate that Britain possesses a weapon of devastating and deterring power; and, as Mr Angus Maude puts it,[2] "the peculiar effectiveness of the H bomb as a deterrent . . . is that it is a total destroyer." Before the Bermuda conference, few people doubted that at least one full scale hydrogen bomb was on the programme for Christmas Island, around which an enormous danger area had been outlined. With a wider realisation of what radioactive fallout may conceivably do and, more specifically, of the ignorance of the ultimate effects of even small doses of strontium 90 on bone and blood, opposition to continued nuclear tests has hardened. And the Government may have been constrained by the vehemence of the protests to modify the tests.

For those who fear, as we do, that the radioactive accumulation from thermonuclear explosions may be near the danger point, there can be little lasting comfort in the news that British bombs are small bombs, while the action of other countries remains in doubt. The only course that does not involve risks which, in relation to mankind as a whole, are utterly unjustifiable is for the three governments so far concerned to stop thermonuclear explosions of all kinds. Proposals for limiting or abandoning tests have had to be revised because it is now apparently possible to hold tests in secret. Nevertheless, we hope the Government will now press forward with negotiations—and with a far greater sense of urgency than they or other governments have shown in the past. Putting the risks at their lowest, continued explosions of megaton bombs can hardly fail in the end to kill a certain number of people by giving them bone tumours that they would not otherwise have had; at worst, accumulated fallout could be responsible for a great many early deaths from malignant disease or other hazards of internal or external radiation of which we know even less—premature ageing is one. Those who are unconcerned at the way bombs have been exploded in recent years are fortified by the belief that the present rate of firing can be continued for a long time without seriously endangering anyone's health. They put their faith (as Mr Macmillan seems to do) in the hypothetical existence of a threshold below which no harm is done. In this belief they may be right; but what matters now is that no one can yet say for certain that they are not very wrong.

EPILEPSY, MIGRAINE, AND SUBARACHNOID HÆMORRHAGE

In the past two decades the syndromes associated with intracranial angiomas have been more clearly defined. This clarification has been largely due to the introduction by Egaz Moniz, in 1929, of cerebral angiography, which enables the condition to be unequivocally diagnosed in most cases. In 1936 Tönnis[1] reported 22 cases investigated in this way. Most of these were studied in Olivecrona's clinic, and in 1948 Olivecrona and Riives[2] reviewed a further 43 cases. Of these, 17 had epilepsy, usually with focal features, as the initial symptom, while subarachnoid hæmorrhage occurred first in 12. The two cardinal clinical features[3] of the condition—focal epilepsy, which may precede other signs by years, and recurrent intracranial bleeding—were thus clearly established. Olivecrona noted one other presenting feature: hemiplegia, either sudden from intracerebral hæmorrhage or insidious by direct involvement of cerebral tissue in the angioma. Mackenzie[4] added episodic headache as a common initial symptom (present in 12 of his 50 cases), and he emphasised that the association of migraine, focal epilepsy, and subarachnoid bleeding which Adie had remarked on in 1930 was sometimes part of the angioma syndrome. Paterson and McKissock,[5] in a careful study of 110 cases, found that 38% presented with subarachnoid hæmorrhage, 26% with epilepsy, 21% with headaches (of episodic "migrainous" type in 15%), and 7% with progressive hemiparesis—thus confirming once more the importance of the triad of subarachnoid hæmorrhage, epilepsy, and "migraine" They observed in 14% of their cases dementia, which Olivecrona had noted to a mild degree in as many as 50% of his Discussing the mode of progression of angiomas they pointed out that, although not neoplastic, these abnormalities can become truly progressive space-filling lesions as small recurrent hæmorrhages result in the formation of cerebral cysts or false aneurysms

These lesions are liable to cause severe disability or even death by sudden severe hæmorrhage or gradually increasing impairment by recurrent epilepsy and dementia Treatment is therefore important Olivecrona was a pioneer in establishing the possibility of radical excision, and McKissock undertook this in almost a third of his cases Ligation of feeding-vessels is less satisfactory and may damage normal brain tissue by general changes in cerebral blood-flow The value of X-ray treatment, in vogue for many years, is dubious, though Potter[6] has recently suggested that it may help It is evident that if these lesions are progressive, as McKissock believes, then prompt diagnosis should be followed by surgical treatment Angiography, the diagnostic linchpin, should always be considered in subarachnoid hæmorrhage, focal epilepsy, and even migraine

RESCUE IN THE MINES

AFTER a mining accident, rescue workers have often to contend with extreme heat and humidity in an atmosphere in which they must use breathing apparatus No laboratory conditions can simulate all facets of an underground disaster, but men can be set equivalent tasks in conditions of high temperature and humidity, like those encountered underground, and they can wear various forms of rescue apparatus while doing them By such means, an attempt has been made to establish limits of tolerance for typical members of rescue teams under anticipated rescue conditions The memorandum by Lind et al,[7] published by the National Coal Board, contains detailed physiological data and consequent recommendations for the guidance of those concerned with rescue teams

The investigation was in two parts, carried out at Oxford and Doncaster The subjects were underground workers, divided into two age groups, 19–31 and 39–45 The Oxford programme was intended to assess the intrinsic individual variations of the subjects, and to compare the reactions of the two age groups to a standard task under hot and humid conditions while not wearing rescue apparatus At Doncaster the men were given a work routine representing a rescue in a mine, to estimate "tolerance-time" in various saturated environments, and to determine any differences in reactions between the two age groups and between men normally employed on different types of mine work In these Doncaster tests the men wore one of two different types of apparatus commonly used in rescue operations

As might be expected, the physiological data show that the older men are less adaptable to stress, for example, their rectal temperature and pulse-rate rose more than those of the younger group under identical conditions But in spite of this, age did not affect the tolerance time, and men from the older group could work hard in hot wet surroundings for as long as the younger men There was no evidence that men in a particular class of pit work were any better or worse physiologically at rescue work than those doing other jobs

On the basis of these data, the National Coal Board memorandum recommends safe working times for rescue teams for a given temperature and humidity—the "confidence limit" If a team exceeds this limit, the possibility of collapse of any member with a low heat tolerance increases No routine medical examination can assess an individual's heat tolerance, and until a suitable heat selection test has been devised, Lind et al think that rescue workers should face hot conditions on their routine practices, so that "heat-intolerant" men may be detected

Though only two instances are reported in the memorandum, tolerance is lowered by minor infections (such as mild food-poisoning and an early head cold) Such minor ailments may prove serious under stress

An appendix to the memorandum sets out the recommendations arising out of the investigations, with details of the precautions to be observed in the conduct of rescue operations, and tables of maximum safe periods of exposure under various specified wet and dry bulb temperatures

NEW SALARY-SCALES FOR DENTAL TECHNICIANS

THE new salary-scales for dental technicians employed in hospitals and local-authority health services[1] probably offset the rise in the cost of living since the previous scales were put into effect, but the remuneration of skilled technicians still seems inadequate, compared with, for example, that of many grades of local-government employees Moreover, the "differential" between the salary of a technician immediately on completion of his apprenticeship (£430, rising step-wise to £535 after six years) and that of a chief technician of many years' experience in charge of a technical staff (£545–760 according to length of service and size of staff) hardly seems to take account of the considerable responsibility involved in the latter post

PRIMARY HEPATIC CARCINOMA

THE incidence of primary carcinoma of the liver judged by necropsy findings, has increased distinctly in recent years Thus, at the Mayo Clinic in 5976 necropsies reported in 1926 the frequency was 0 083%,[2] whereas in 16,303 necropsies reported in 1947 the frequency was 0 19%[3]—more than double that observed twenty years earlier Similarly in Vancouver[4] the incidence doubled in twenty years

These and other figures show that primary carcinoma of the liver is still rare in North America and Europe, but in Oriental countries it is three to four times as common as in the Occident, and in parts of Africa it is no longer rare, the incidence being highest in members of the Bantu tribe The report of the South African Institute for Medical Research[5] that primary carcinoma of the liver was present in 39 56% of all necropsies, and the observation that this tumour constitutes 86% of all primary carcinomas in the natives in the gold mines of the Witwatersrand,[6] are overwhelming evidence of the importance of local factors in this disease The relative importance of racial and environmental factors is still not clear, but the pronounced tendency for the incidence to decrease among Oriental and African immigrants to North America suggests that environment may be the more significant factor, and the most important environmental variable is probably the diet

The relation of dietary deficiency to cirrhosis in both man and laboratory animals is now well established The association of primary carcinoma with cirrhosis of the liver is equally well established cirrhosis is present in about 80% of cases of hepatocellular carcinoma and in about 30% of cases of cholangiomatous carcinoma In under-privileged communities the high incidence of primary hepatic carcinoma is doubtless attributable mostly to the high prevalence of hepatic cirrhosis. The enhanced incidence of primary carcinoma of the liver in North America and Europe during the past decade is paralleled by an enhanced frequency of hepatic cirrhosis. MacDonald's figures from the Boston City Hospital,[7] for example, show that, whereas in each decade from 1917 to 1946 hepatic cirrhosis was found in about 8% of all necropsies, in the eight years from 1946 to 1954 this figure was almost doubled; and primary carcinoma of the liver increased correspondingly from 0.34% to 0.72% of all necropsies. It is unlikely that the enhanced prevalence of cirrhosis in these areas is due to lowering of the nutritional status.

[6] Berman C Primary Carcinoma of Liver London 1951

MacDonald finds that of seven varieties of cirrhosis into which the cases were classified, two account for most of the increase—namely, nutritional cirrhosis, whose increase is almost certainly the result of increased alcohol consumption, and healed yellow atrophy, an increase of which was to be expected in view of the widespread epidemics of infective hepatitis in recent years. A surprising finding, however, is the frequency with which primary carcinoma develops in the liver scarred as a result of acute yellow atrophy. Mallory[8] reported in 1932 that carcinoma developed in 3 out of 46 cases of healed yellow atrophy, compared with 4 out of 49 cases of hæmochromatosis and only 5 out of 454 cases of other varieties of cirrhosis. MacDonald has now found carcinoma in 13% of 222 cases of healed atrophy, the frequency among cases of other forms of cirrhosis, excluding hæmochromatosis, remaining at the usual low level of about 2%. The reason for this enhanced tendency towards malignant change in the liver after recovery from acute massive necrosis is unknown. Discovery of this reason might throw much-needed light on the mechanism of the well known sequence of injury, repair, hyperplasia, neoplasia that takes place not only in the liver.

METHONIUM AND PULMONARY DISEASE

THE development of pulmonary disease in hypertensive patients treated with methonium was noted by Doniach et al.,[9] and Perry et al.[10] now report the results of further investigations into this matter. They examined post mortem the lungs of two groups of patients in whom an anatomical diagnosis of arteriolar nephrosclerosis had been made. The first group of 67 patients had never been treated with methonium compounds; the second group of 27 patients (who died later than the first) had all received at least 30 g. of methonium salts in their last month of life. The groups were comparable in age and type of disease. It was found that the lungs of a proportion of the patients in both these groups showed fairly constant histological features—intra-alveolar fibrin masses, with a striking tendency to fibrous organisation, and hyaline-like membranes lining the walls of alveolar ducts and atria. But the lungs in the methonium-treated group were almost twice as often affected as those in the untreated group (59% compared with 34%). This condition, termed "fibrinous pneumonitis" by Perry et al., has been observed in uræmia[11 12] and rheumatic fever,[13-15] and in order to separate if possible the effects of uræmia from those of methonium therapy an analysis was made of the clinical findings in 59 patients in the two groups who had been diagnosed during life as suffering from malignant hypertension (supine diastolic pressure greater than 120 mm. Hg at rest, hæmorrhagic and exudative retinitis with papillœdema, and severe renal disease). 19 of these patients belonged to the methonium-treated group and 40 to the untreated group. Whereas fibrinous pneumonitis was not found in untreated patients whose non-protein nitrogen never exceeded 60 mg. per 100 ml. plasma (normal 25 mg. per 100 ml. by the method used), it was seen in 9 methonium-treated patients with non-protein-nitrogen levels below this figure. It was inferred from these results that methonium compounds, like the retained nitrogenous products of uræmia, may precipitate in hypertensive patients an attack of fibrinous pneumonitis.

Doniach et al.[9] do not consider that this lung condition can be attributed directly to methonium; they think that its probable basis is pulmonary œdema, due to attacks of left-sided heart-failure, modified by intermittent lowering of the blood-pressure by the drug. Perry et al.[10] investigated the effects of a raised pulmonary capillary pressure by examining post mortem the lungs of 39 patients who died from severe, or moderately severe, mitral stenosis. They did not discover fibrinous pneumonitis of any extent, though they found small patches of it in 18% of cases. Epstein and Greenspan[16] similarly examined the possibility that heart failure was responsible for the "fibrinous pneumonitis" sometimes associated with rheumatic fever, by looking for the characteristic but non-specific pathological picture in the lungs of 59 patients dying of pulmonary congestion caused by hypertension, coronary thrombosis, or mitral stenosis without active rheumatic infection. The only instance they found was in a patient with hypertension complicated by uræmia. Perry et al. could also find no clinical evidence of left ventricular failure in patients with fibrinous pneumonitis: dyspnœa was usually relieved, not exacerbated, by putting the patient supine, and circulation times and venous pressures were relatively normal. The most striking clinical feature in these attacks was the rapid respiration rate, and, since the minute volume was often much increased in the presence of a normal carbon-dioxide content, pH, and oxygen saturation of the arterial blood, interference with blood gas exchange by the fibrinous pneumonitis was the most likely explanation of the respiratory distress. Perry et al., therefore, believe that methonium salts, like uræmia and rheumatic fever, may cause fibrinous pneumonitis by damaging the pulmonary capillaries so that they leak exudate into the alveoli; and they do not think that left-sided heart failure is an important factor, although it is admittedly difficult to exclude it altogether.

Whatever the exact ætiology of fibrinous pneumonitis in methonium-treated hypertensive patients may prove to be, it is well to remember that this condition may easily be overlooked as a cause of respiratory distress, since physical signs are few, even when chest films show widespread changes in the lung fields.

REMUNERATION

A DECISION to recommend refusal to cooperate with the Royal Commission on the remuneration of doctors and dentists was reached by the council of the British Medical Association on Wednesday, March 27. This news was given at a press conference on the following day, when it was announced that the council is also recommending that the association should institute its own comprehensive review of State medical services, with the aim of eradicating "those faults of the present system which cause dissatisfaction to the public and frustration to the profession." Lay persons of high standing are to be invited to sit with medical members on the committee of inquiry. Both these recommendations are to be put to the association's representative body on May 1.

DAY HOSPITALS AND NIGHT HOSPITALS IN PSYCHIATRY

ARTHUR HARRIS
M.A., M.D. Manc., D.P.M.
PHYSICIAN, BETHLEM ROYAL HOSPITAL AND THE MAUDSLEY HOSPITAL, LONDON

A DAY hospital is a place in which patients spend a substantial portion of their waking time under a therapeutic régime and from which they return to their own home or hostel to sleep at night. Soviet Russia has had day centres as departments of its neuropsychiatric dispensaries at least since 1942. In the Russian centres the emphasis is on occupation and rehabilitation for work, although hospital facilities are also provided (Wortis 1950). The first day hospital in the English-speaking world was started in Montreal (Cameron 1947, 1956), as part of a psychiatric teaching hospital, the Allan Memorial Institute. Since then only two have established themselves firmly in North America, one in the Montreal General Hospital, a large general hospital with a psychiatric department (Moll 1953a and b), and one in the Menninger Clinic, Kansas (Law 1947, Barnard et al. 1952). Several attempts in State mental hospitals in the U.S.A. have proved abortive. But the idea is spreading, and a day hospital operating successfully among primitive people in tropical Africa has lately been described (Lambo 1956).

In England the first day hospital was started in London as an independent institution unconnected with any existing hospital (Bierer 1951). Since then the number has slowly increased. Some follow the original London model (Aron and Smith 1953), some—such as the Bethlem and Maudsley ones—the Montreal pattern. Some cater for specialised groups of patients, such as old people (Cosin 1955) or chronic unemployable neurotics (W. Mayer Gross, personal communication). They differ in outlook and methods. There is no uniformity, for example, in the amount of time that each patient spends at the day hospital. In some, as at Oxford, one afternoon a week may be thought adequate for some patients (Cosin 1955), in others, as at Bethlem and the Maudsley, five days is the minimum for all patients.

Bethlem and Maudsley Day Hospitals

Bethlem Royal Hospital and the Maudsley Hospital together form a postgraduate teaching hospital which caters for all types of psychiatric illness except uncomplicated mental deficiency. Although administratively one hospital, the buildings are 8½ miles apart. The two day hospitals, one at Bethlem and one at the Maudsley, function essentially as wards whose special characteristic is that the patients go home each evening. In other words patients can readily pass from the conventional inpatient wards to the day hospital and from the day hospital to the inpatient wards as their condition requires. In practice, however, most of the day-hospital patients spend their illness in the day hospital and are not transferred to or from the ordinary wards. All the diagnostic and therapeutic facilities of the joint hospital are open to them, and the only forms of psychiatric treatment which it has proved impossible to undertake in the day hospital are deep insulin coma, continuous narcosis, and neurosurgery. Each day hospital takes 30 patients at a time and has some 100 to 150 admissions a year.

The Maudsley day hospital was opened in May, 1953, and is within the grounds of the hospital in the ground-floor and basement of a Victorian house which had been used as a nurses' hostel (Harris 1954a and b). The day hospital at Bethlem was opened in April, 1956, and is housed in a pavilion which used to belong to a sports club (Harris 1956). Each has a large room where men and women patients can mix and undertake group activities, such as discussions, games, and play-readings. There are two smaller rooms, one for men and one for women, where the more ill patients can spend their time quietly without too much social pressure. Two rooms for doctors, an office for the nurse in charge, and lavatories complete the indoor accommodation. There is also a tennis court and grounds in which the patients can walk and play. The Bethlem day hospital, which is farther from the main hospital and therefore has to be more self-contained, also has a kitchen, extra interviewing-rooms for psychologists and social workers, and a hut for the administration of electroconvulsion therapy, with a waiting-room, treatment-room, and recovery-room.

The day hospitals are open from Monday to Friday and closed on Saturday and Sunday. The patients arrive about 8.30 A.M. and leave about 5.30 P.M., or at times that fit their relatives' hours of work and convenience. They pass their day in much the same way as the patients in the less acute conventional wards, the morning generally being given over to occupational therapy and the afternoon to group activities. But the programme at the day hospital is readily varied to meet the need of individuals. For example, those unsuited for group activities continue with occupational therapy in the afternoons. Shopping parties, in the company of a nurse, enable patients whose families are all out at work to return home with the household supplies. If a night sedative is needed it is handed to a relative who sees that the patient takes it at home.

Staff

The medical care for each hospital is provided by a senior psychiatrist (giving one session a week), a full-time registrar or psychiatrist in training, and one or at times two clinical assistants. The nursing care is provided by a doubly qualified ward sister and two junior nurses, who are staff nurses or student nurses according to the training situation at the hospital at the time. The part-time services of a clinical psychologist, a psychiatric social worker, and an occupational therapist are also available. Nurses find work in the day hospitals congenial, because the simple type of organisation and absence of bed linen and other stores relieves the ward sister of administrative duties and enables her to give the greater part of her time to the patients directly. As there is only one shift, the nurse is in close contact with the whole of the patients' hospital life, and this increases her sense of responsibility and personal influence. The relatives chat and ask advice when they bring and collect the patients, so that the nurses are brought into the family situation as well.

Patients

In selecting patients one of our chief criteria has been that the patient must be so ill as to need admission to a hospital bed if the day hospital did not exist. We have closely adhered to this: all our patients are so far incapacitated by their illness as to be unable to work or lead their normal lives and most are unfit to be left alone at home during the daytime. On the other hand the patient must not be so disturbed as to be too difficult for his family to manage at night or for them to bring him and fetch him. He should not live much more than half an hour's journey away, for arrangements will break down if too much travelling is involved. Sensible, stable relatives, with affection and concern for the patient, who are willing to play an active, supporting rôle, are a very great help, and in their absence day-hospital treatment is likely to prove difficult, though success has been achieved in some unfavourable family situations. Harassed, overworked housewives, with no one to take their burdens, who try to cram their housework in during the evenings, do not do well and usually have to be admitted as inpatients With experience we have found that a very large proportion of potential inpatients can be treated on day hospital lines, and the pressure of recommended admissions is now greater on the Maudsley day hospital than on the wards

Advantages of the Day Hospital

The advantages of day-hospital treatment are economic and social It has been found at the Maudsley that the running costs of a 30 place day hospital are roughly one third of those of a 30 bedded ward, and Montreal experience is similar There is only one nursing shift instead of three and no bed-linen or dormitory space are needed Also kitchen and domestic staff are needed for only a short time The saving in capital costs is even greater, for new building is unnecessary and existing buildings can be adapted Thus the day hospital at Bethlem was bought, reconditioned, furnished, and equipped for little more than the cost of one bed in a new hospital

The patient keeps his place in the family—a very important matter for the middle aged and elderly who form the bulk of the day-hospital clientèle Such people's homes tend to disintegrate if they are brought into hospital as inpatients

Treatment tends to be shortened, for it is no longer necessary to test the patient's reaction to his normal environment by sending him home for half days and then weekends 60% of patients in the Maudsley day hospital suffer from depressive illnesses and two groups of depressed patients, under the same physician and matched for severity and other relevant features were compared One group was treated for the whole period of the illness in the day hospital and the other in the inpatient wards, and the average stay of the day-hospital group was between two and three weeks less than that of the inpatients (M J Craft, personal communication)

Some women present an intractable social problem, because owing to phobias or other symptoms they cannot be left alone and there is nowhere for them to go while their husbands or other relatives are at work In the absence of the day hospital they must be admitted into hospital (with the risk that their homes will break up), or their husbands must give up their jobs, which usually causes poverty, resentment, and unhappiness These patients are successfully handled in the day, hospital, though many require long treatment—up to one or even two years

Other people whose difficulties the day hospital has solved include a woman who might have lost the custody of her child if she had left home altogether, and a hallucinated paranoid patient who refused to stay as an inpatient but attended the day hospital until she recovered, so that certification was avoided

Night Hospitals

At the Montreal General Hospital there is a night hospital to which the patients come after their day's work, they spend the evening there, have any necessary treatment, and then sleep until it is time for them to go to work the next morning (Moll 1955) The Maudsley night hospital, which opened in August, 1956, is not for patients undergoing active treatment but for those who have partially recovered and are working though not secure enough to live in ordinary lodgings or hostels For many years it has been the practice in the joint hospital as in several other psychiatric hospitals, to allow suitable patients to go out to work and return to the hospital in the evenings Their adjustment to the outside world is easier if they can make it in two instalments, first to the job and then to normal living conditions These patients are now collected in the night hospital, which uses the day hospital accommodation as sitting rooms and the bedrooms upstairs for sleeping—an economical use of this Victorian house One nurse stays on from the day hospital to receive them on their return from work, they see their doctor once a week, and they attend the evening amusements and social events arranged for the inpatients if they wish There are 14 bedrooms—one floor for men and one for women Patients usually settle in their jobs and leave the night hospital after a *few* weeks

Comment

These developments are in line with the feeling which is growing up, not only in psychiatry but in other branches of medicine also, that patients are sometimes isolated in hospital more often and for longer than is necessary Social considerations and the possible harmful effects of a stay in hospital are receiving more attention

Varying patterns of day hospital can be designed to suit different types of parent institution In the new Montreal General Hospital inpatients and day patients share the same psychiatric ward, and this model might well be copied by psychiatric departments of general hospitals in this country, which are usually situated in large centres of population and are therefore better placed than most mental hospitals to run day hospitals

A BANK of freeze dried bone established in Leeds in April, 1955, has supplied grafts to about 80 patients, of whom 46 are reviewed here, the remainder having been operated on too recently for final radiological assessment

Collection and Preparation of Bone

Bone is taken from donors aged up to 30 A considerable amount of cancellous bone is obtained with the minimum of difficulty from the lower end of the femur and the upper end of the tibia The limb is draped as for

Short-term clinical results, the ease and convenience of use, and the shortening of operating-time resulting from the use of freeze dried bone, in our opinion, justify the wider application of this method

We are indebted to the Board of Governors of the United Leeds Hospitals for a grant towards apparatus, expenses, and maintenance of the bank One of us (K Z) has been in receipt of a grant in aid of expenses by the Medical Research Council We are indebted to Mr A B Pain and Mr J M P Clark for their support and encouragement in this venture and for allowing us to record the clinical results All the patients in this series were under their care

OXFORD PLANS

AFTER nearly five years of close study a subcommittee of the board of governors of the United Oxford Hospitals has worked out a plan which is described as "not a directive to expand but a demonstration of the boundaries within which it would be advisable to confine future expansion "[1]

The group of eight hospitals combined under the National Health Service Act to form the United Oxford Hospitals now has some 1260 beds These hospitals provide $1^1/_2$ million people with general medical and surgical services, while in some specialties such as plastic surgery and neurosurgery the population served may be as big as 5 million

The oldest of these hospitals is the Radcliffe Infirmary, which was opened with two wards in 1770 as an integral part of the faculty of medicine in the university The munificent endowment of more than £2 million from Lord Nuffield in 1937 established the Nuffield chairs and departments of medicine, surgery, obstetrics and gynæcology, and anæsthetics, and later at the Wingfield-Morris Hospital a chair of orthopædics The Nuffield Provincial Hospitals Trust established later the professorship and department of plastic surgery These new units primarily for research and postgraduate teaching had to be integrated with the existing organisation of a county hospital Then the clinical school was given great impetus in 1939 by the war time need of students completing their medical course out of London This complexity made imperative an examination of the medical work and teaching, research, and nursing services and of the board s relations with the regional board and other bodies

The main development is envisaged at the Radcliffe Infirmary, which is to be enlarged from 498 to 733 beds Each specialty in the divisions of medicine, surgery, obstetrics and gynæcology, and laboratories is discussed in turn, and the dental requirements are considered separately The Nuffield departments are to be integrated geographically and their consultants will be members of the hospital "firms", and it is proposed that one consultant in each specialty should be part-time to promote closer professional contact with the general practitioners The laboratories are now scattered and poorly housed, these need new buildings, and some units such as the Nuffield department of anæsthetics will have their own The outpatient department, at present sadly inadequate, will need a new block

The Churchill Hospital will be increased from 283 beds to some 440, and the neurological, respiratory and dermatological units will be here The Slade Hospital may be used for convalescents The Cowley Road Hospital will continue to accommodate the elderly sick, both acute and long term Large capital expenditure is turning this hospital, once a workhouse with a visiting doctor, into a modern geriatric unit, including a rest home and a day hospital The Eye Hospital, modernised between 1948 and 1950, needs only minor modifications

As regards medical teaching the subcommittee remarks that perhaps if the preclinical students were better informed about the fundamental research work carried out in the clinical departments, more of the abler students might take their clinical course in Oxford The preclinical departments are closer in both situation and organisation to the other scientific university departments than to the clinical school

It is not easy to balance the essential work to be done by the nurses and their own welfare and educational needs, and the subcommittee suggests that a director of nurse training should coordinate the theoretical and practical sides of their training

This stimulating report ends with a firm statement that the basic aim of its recommendations has been to ensure a steadily rising standard of hospital care, and that "there must never in a teaching hospital be any conflict between the claims of research and teaching, on the one hand, and the care of the patient, on the other"

NATIONAL HEALTH SERVICE ESTIMATES

THE estimated total net cost of the National Health Service in England, Wales, and Scotland in 1957–58[1] is £550,136,745—an increase of £21,236,715 on the cost in the present year Of the estimated gross total of £630,196,495 in the coming year, the hospital services take up £404,442,415—an increase of £17,744,900 This increase is mainly accounted for by increases of £11,011,000 in the allotment to revenue accounts (total £371,537,000) and of £5,622,000 to capital accounts (£20,524,000)

The cost of the general medical, dental, pharmaceutical, and supplementary ophthalmic services in 1957–58 is estimated at £177,641,830—an increase of £3,208,175 This increase is due mainly to increases of £2,831,500 in the cost of general dental services (total £38,526,500) and of £1,415,000 in the cost of general medical services (£67,214,000)

Public Health

Accidental Deaths

PROVISIONAL figures of deaths from accidents are to be published monthly in the *Registrar-General's Weekly Return* Detailed figures of accidental deaths during each quarter will continue to be published regularly in the *Registrar-General's Quarterly Return* The first of these monthly reports appears in the weekly return for March 30, which gives the following figures for January, 1957

The total number of accidental deaths was 1377 Of the 730 deaths from home accidents, 481 were due to falls There were 413 deaths from road accidents, 219 of which were of pedestrians Deaths due to other transport accidents numbered 51 Deaths from all other accidents numbered 183

Of the 1377 deaths, 97 were of children under fifteen years of age and 766 were of persons aged sixty five or over

Eire in 1956

In Eire last year[2] the birth-rate was 21 0 per 1000 population, and the death-rate was 11 7 per 1000, the death rate from all forms of tuberculosis was 0 24 per 1000 The maternal-mortality rate was 0 82 per 1000 births registered The infant-mortality rate was 36 and the neonatal-mortality rate 23, per 1000 births registered

In England Now

A Running Commentary by Peripatetic Correspondents

ALL honour to your Dip Ski correspondent returning prize-laden to these shores from the Alpine snowfields, his malleoli intact, all cares blown away from his 50-odd years. Alas, I have a different story to tell. My roaring 40s seem to be giving way prematurely to the frailer 50s. My muscular tone is not what it was for retention of an upright posture, or for much else.

As this is the season for travellers' tales, I will simply say that I have just come back from a mountain-rescue course high in the Norwegian snows. It was a fine mixture of first-aid and survival techniques. Praying fervently against a personal need for first-aid, I concentrated wholeheartedly on survival. Although no slalom certificates adorn my desk, I have a pretty little silver snowflake badge in my lapel. It seems I went in deeper and oftener than anyone else.

One of our exercises was to build an igloo and prove our worth by spending the night in it. There were six men and a girl in my group; so out we went on to the mountain, and spent the afternoon cutting snow-blocks with a saw. By 6 P.M. the igloo was made and we all crawled inside. Although the aperture was none too generous for my statistics, a friendly Scandinavian shove on the buttocks finished the job. We crouched together by candlelight over our tins of soup while the thermometer remained immovable at −12°C. The Norwegians bobbed in and out to pay social and other calls around the neighbouring igloos. I could not be bothered to thaw out my frozen boots, so I perched crosslegged on my little nest of fir branches and bowed international good will to passers-by. About 9 P.M. the last of my companions came to roost and sealed up the doorway with a huge snow-block. They dressed or undressed for bed as fancy pleased, wriggled into their sleeping-bags, and with a final round of wisecracks snored happily off into oblivion.

It was my fate to try out a paper casualty-sack instead of a proper sleeping-bag. As sleep appeared unlikely I resigned myself to a twitching vigil. At 1 A.M. signals started thawing their way from the hypogastrium through my semi-frozen spinal cord. At 2 A.M. the afferent warning-system was red hot. The cerebral cortex wondered what to do. A rather brash association-area cell suggested airing my proudly learnt phrase-book question *Hvor er et Toalett?* But the answer was too obvious. Gents' or Ladies, there were none. I crawled out of my paper torture-bag and squeezed into my frozen boots. Six Norwegians stirred uneasily in their dreams. I lit a candle and crept on all fours over their bodies to the door. A pretty question then arose: should I leave the candle inside the igloo to find my way back, or should I take it in case I froze up? My previous efforts with a blowlamp on British plumbing had been so disastrous that the candle seemed best as a homing beacon. I tugged at the snow-block door in vain; we were frozen into our ice-chamber. My elbow knocked over the breakfast billycan. Greta alone turned over and groaned. The thought of having to enlist the fair help of the only Norwegian with any reflexes left sent a panic surge of adrenaline to heave away the snow-block and dive towards the night.

I started the second stage as an R O A with extended legs, a malpresentation which jammed at the igloo brim. Involuntary fœtal cries awoke the rest of the litter. They stared with sleepy incredulous eyes at to what from their angle was a mad English breech. My polyglot repetition of "Toilett! Toilet!" produced only shrieks of bawdy merriment.

A further interchange of simple guide-book phrases resolved their doubt as to whether I was coming or going. I rather feared that they might try to hook out a leg, but after much bearing down from the fundus, a cry of *En, To, Tre!* produced a strong contraction, and I was delivered into the same old cold hard world. That mountain snowfield looked very beautiful under the full moon. Sixty seconds later I had the strange experience—like running back a bizarre midder teaching film—of returning as a high forceps retrograde R O P, given a slick internal version, and commanded to close the so-and-so cervix until reveille sounded full term.

* * *

We had always thought that curfews were only to be found in textbooks of medieval history, but they are quite the fashion again these days. We had one in our part of the Orient when we had our bit of rioting last autumn, and one or two people found it highly embarrassing.

For example, there was the inpatient in one of the local hospitals who leaned so far out of the window to see how the riots were getting on that he fell out into the street. He hammered at the doors in an endeavour to get in again, but received no sympathy from the doorkeeper, who stoutly maintained that his orders were to admit riot casualties only—and the patient obviously didn't come into that category. The police who found him in the street outside the hospital, however, took an entirely different view. They considered his story that he had fallen out of a hospital window improbable. Unfortunately he had a bandage round his head owing to a bit of surgical treatment: to the police this was clear evidence that he had been taking part in the riots—and here he was breaking the curfew! So off he went to gaol, and it took him a couple of days to convince the authorities of his innocence.

A more proper respect for the law was shown by a small boy who was on probation. He had to report to the police-station every Thursday. On the Thursday in question the police-station happened to be in the centre of what was almost a pitched battle, but the boy boldly made his way there through shot and shell (or whatever it was that they happened to be using at the time) and presented himself in the proper manner. If his delinquent tendencies can be controlled that lad should go far.

* * *

However much I eat I am still hungry in my stomach and I still lust for food in my mind. I cannot sate appetite either physically or mentally, though normally I am bored by food. Today for lunch, until now always a very light meal, I ate 1 lb of fat ham with a 2½ oz slab of butter on my bread, ½ oz of olive-oil on my lettuce, and some apples. I ceased eating not because I had scoffed 3000 calories but because I felt filled, though still hungry. Now, half an hour later, even the pleasurable feeling of being full has faded away. I should like another lunch. I hanker for food as I go to sleep, I yearn for food as I wake. As I enter the Royal Society of Medicine library I catch myself looking to see if there is any food about though in twenty-five years I have never seen even a sweet there. I shall myself now go out to post this to *The Lancet* purely as an excuse to pass a shop where I can buy four smoked buckling and two large Belgian sausages to add to my light afternoon tea. Prednisone tablets at £6 a hundred may be nothing to the N H S, but the appetite they induce is bankrupting me.

* * *

Jane was a bright young lady of 3½ years who peered through the bars of the cot and never missed anything that went on in the ward. When she had been there for two or three months, and was by far the oldest inhabitant of the ward, the pædiatrician suddenly struck his brow with his palm and declaimed: "Jane must have occupational therapy." The registrar and houseman set to work, and at last persuaded the unwilling occupational therapist to venture into the children's ward—an unprecedented feat.

Next day the houseman called on Jane, and found her with a little tin on her knees. The tin was neatly labelled "Occupational Therapy". "What's this, Jane?" he asked.

"Rubbish," she said.

Do they really mean it?—In the paper on Papworth's results (*Lancet*, March 9, 1957, p. 521) the following frank marital statistics are given:

Reasons for Leaving Prematurely

409 (47%) ended their training prematurely for the following reasons:

To take other work	120
To a different training course	23
Marriage	15
Other domestic troubles	61

Letters to the Editor

THE HUMAN USE OF ^{22}Na

SIR,—Dr Martin and his associates in your last issue draw attention to the great advantages of the use of ^{22}Na in the study of sodium metabolism There is no doubt that it could be of the greatest assistance in the investigation of many clinical problems They rightly comment on misgivings about the use of this long half-life isotope in man Clearly, the danger depends on the extent to which it may be retained in the body

In the course of an experiment in September, 1955, on one of ourselves, after a dose of 50 microcuries of ^{22}Na, we followed changes in sodium metabolism using both the cumulative balance technique and the whole body counter In addition we attempted to study sodium exchange in the patella by an external counting technique The results suggested that a small portion of the dose was taking part in an extremely slow exchange with a fraction of the sodium in bone

The external counting technique indicated that the effective half life of the ^{22}Na in the body at the end of fifty days was approximately ten days This method was not sensitive enough to give an accurate measurement of the residual activity of the body after a long period Observations have been made, however, in the high-pressure ionisation chamber system of the Department of Medical Physics at Leeds The following figures have been obtained with this instrument by Dr P R J Burch, Medical Research Council fellow

Days after injection of ^{22}Na	*Body content of ^{22}Na*
256	0 055 µc
290	0 052 µc
469	0 031 µc

We are grateful to Dr Burch for allowing us to quote his observations

The results suggest that the body retained over a long period about 0 1% of the injected dose, which has a biological half life of approximately one year

The radiation dose involved in this test is of the order of 0 8 rads to the whole body from the radiosodium undergoing turnover in the extracellular fluid For the very slow phase in bone, the dose is bigger, but if it be assumed that the specific activity of that sodium in the bone involved in the long term exchange approximates to that of the plasma at its highest value, a dose of 14 0 rads appears to be the upper limit in the small volume of bone in which the ^{22}Na is deposited

This radiation dose is in the range which may be hazardous, though the matter is at present controversial Nevertheless, the dangers associated with long-continued irradiation of bone are well recognised

In view of these results it would seem advisable in future to limit the use of this isotope in clinical investigation to special circumstances where information essential for treatment of the patient is not otherwise available

HOSPITAL MEDICAL RECORDS

SIR,—Dr Skelton (March 30) urges the permanent preservation of hospital records and X-ray films and concedes that "the practical problem revolves around the question of space required for their storage"

This 560 bedded general hospital stores the X ray films of five years on 876 cubic feet of steel shelving costing £240 in a permanent brick building (with steam heating) of 2600 cubic feet capacity, estimated to cost £500–600 and representing approximately 7% of the cubic capacity of the X-ray department

These figures give some idea of the magnitude of the problem and the expense involved should be equated to the intangible value of the records preserved While hospitals are urgently requiring more space, the claim of the patients is greater than that of the records

Ashford Hospital,
Middlesex

J A BROCKLEBANK

DISCREPANCIES IN THE ERYTHROCYTE-SEDIMENTATION RATE

SIR,—In their paper of Feb 2, Dr Alexander and Mr Andrews make no reference to previous work on this subject

When Westergren [1–3] adapted the sedimentation test of Fahraeus,[4] he showed by careful experiments that a tube of 200-mm length and 2 5 mm bore was adequate for the sedimentation of blood using 3 8% sodium citrate solution as anticoagulant Wintrobe [5] introduced the hæmatocrit tube for determining the packed cell volume of blood and for this purpose a solid anticoagulant had to be used He first used potassium oxalate but subsequently [6] used the ammonium and potassium oxalate mixture of Heller and Paul [7] to obviate correcting for the shrinking of the erythrocytes caused by the former anticoagulant Wintrobe suggested that the hæmatocrit tube could also be used for determining the erythrocyte sedimentation rate (E S R) and correcting for anæmia, but it is now evident that not sufficient experiments were carried out to ascertain that the tube length and bore were adequate for the sedimentation of blood when the anticoagulant was changed from 3 8% sodium citrate solution to solid oxalate mixture

One of the first to doubt the advisability of using oxalated blood for determining the E S R was Schuster,[8] who showed that sedimentation was irregular when the bore of the tube used was less than 3 5 mm and when a high red cell count was combined with rapid sedimentation Schuster also described a lag in the sedimentation of oxalated blood Others [9–12] subsequently reported anomalous E S R readings using the Wintrobe method and were of the opinion that the original Westergren method gave a better indication of the clinical state of a patient

Goldberg and Conway [12] showed that the factor concerned in the irregular sedimentation was that of dilution, for when oxalated blood as used in the Wintrobe method was diluted with isotonic saline, E S R readings were similar to those using the Westergren method I observed similar irregularities with both heparinised and oxalated blood in Westergren tubes, and showed that this was due to a prolongation of the aggregation phase of sedimentation As this phase was observed to end suddenly with the formation of large rouleaux aggregates and followed by rapid sedimentation, I considered that it was due to a metastable state and suggested that the condition might be a hysteresis phenomenon [13] Alexander [14] showed that a delay in sedimentation may be caused when the tube wall above the meniscus of the blood is not previously wetted—the "reflux factor" Subsequently, Lewi and Clarke [15] showed that this phenomenon occurred when the packed cell volume and the "rouleaux formation intensity" of the blood are both high

On the Continent, irregularities in the sedimentation of undiluted blood have been studied by Östner,[16] Horányi,[17] and Mårtensson and Hansen [18] The last mentioned have termed these irregularities the "reversed E S R" because the sedimentation of undiluted blood is often less than when diluted with isotonic saline They have also shown that the bore and length of the Wintrobe tube is inadequate for the sedimentation of undiluted blood and that for unimpeded sedimentation the tube bore has to be at least 5 mm and the length greater than 200 mm

For the past two years we have been determining the E S R by both the Westergren (3 8% sodium citrate solution) and Wintrobe (heparin) methods We have found many discrepancies between the two readings—invariably there is a delay in sedimentation in the Wintrobe tube As also observed by Dr Alexander, we find that these discrepancies are not confined to any specific disease They occur when the "rouleaux formation intensity" and the packed-cell volume are high The conditions that frequently have a potentially high E S R, and in which we have found discrepancies, are rheumatic fever, rheumatoid arthritis, tuberculosis, and multiple myeloma On several occasions a case of myeloma has first been suspected when there has been a gross discrepancy between the two methods We consider that the Westergren method gives a better and more reliable indication of the clinical state of the patient We use the Wintrobe method as well, partly for interest and partly so that a correction for anæmia can be obtained

REFLECTIONS ON CIRCULATORY CONTROL

SIR,—I should like to express my firm endorsement of Dr Brown's remarks (March 23) on the use of hypotensive anæsthesia in neurosurgical practice

From 1949 to 1952 in the Bristol Neurosurgical Unit, hypotensive anæsthesia by arteriotomy, or occasionally by ganglion-blocking drugs, was used in selected cases of (1) cirsoid aneurysms and aneurysms of the main cerebrovascular tree, and (2) vascular tumours, or tumours in which considerable intracranial tension was already present, and in which the diminished hæmorrhage and brain shrinkage achievable might be an advantage

From the beginning of 1953 till now normotensive anæsthesia, but with the addition of controlled respiration by mechanical means, and latterly the routine use of premedication with hypertonic sucrose solution whenever there was papillœdema, has been used in almost all our craniotomies Postoperative recovery has been more rapid, and cerebral œdema either during or after operation has virtually disappeared The operating conditions obtained by simple light anæsthesia, elevation of the head end of the table, and controlled respiration have been as good as—and often much better than—those obtained with safe degrees of arterial hypotension, the period of reactionary oozing which tends to follow restoration of normal blood-pressure, and which must surely be a reaction to relative ischæmia, is not seen, and wounds do not now need to be reopened for the removal of postoperative clot

The brain in a vascular sense resembles an incarcerated hernia Strangulation, caused by failure of adequate venous drainage due to compression of veins, leads to a neurosurgical emergency Owing to the use of scalp and diploic channels as emergency drainage in many cases of cerebral tumour, venous impairment is made worse by craniotomy until decompression is achieved

Manually assisted respiration alone aids in avoiding congestion If mechanical respiration with negative phase apparatus is used, intracranial tension can be reduced below preoperative level, and often without recourse to lumbar or ventricular drainage, The arterial vascularity of the brain appears unimpaired, and blood-pressure is maintained Hypertensive patients with evidence of arteriosclerosis can be anæsthetised thus, be allowed to remain hypertensive, and bleed no more than normotensive patients

The fatal lesion is compressive ischæmia In the presence of this threat, it does not seem wise to reduce arterial blood pressure until decompression has been achieved (when it is no longer necessary anyway) if comparable results can be obtained by any other means In cases where there is no intracranial lesion, the use of hypotension in anæsthesia for particular types of surgery may well be justified, though personal experience has shown that what is applicable to neurosurgery is also applicable to other cases in which a relatively bloodless field is required

Bristol
P L F MORTIMER

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—I, too, would like to congratulate Dr Ackner and his colleagues on one of the first truly scientific attempts to assess the value of deep insulin therapy in schizophrenic patients (March 23)

There is, however, one reason for reserving judgment on this controversial subject, and that is the short follow-up period, which, it seems, never exceeded 2 years, and in some cases was only 6 months

If this and similar investigations show that deep insulin treatment has no specific effect in schizophrenia, and it is discarded wholesale by mental-hospital staffs, I hope that one aspect of this particular study will be borne in mind—that each patient received active therapy and enthusiastic attention The danger seems to be that deep insulin therapy will be discarded and nothing put in its place, except perhaps a half-hearted trial of some of the new drugs, such as chlorpromazine, which may or may not be successful

London, S W 16
R D WATSON

SIR,—In the interesting report by Dr Ackner and his colleagues of a controlled trial of insulin in schizophrenia, the analysis does not permit any unique conclusion It shows both that the results could have been due to chance and that the failure-rate, in terms of not being discharged, was, most likely, almost halved in the insulin group

Consider the nature of the data, and, for simplicity, consider only the failures, and suppose the control sample, with 10 failures out of 25 to be typical, so that one need only consider the sub-set of possible trials of the form

	Control group	*Insulin group*
Discharged	15	$25 - a$
Not discharged	10	a

where a is the number of failures in the insulin group

Now the proportion of failures in the insulin group is $a/25$ and the failure-rate, compared to that in the control group, is $a/10$ Yet even if insulin did halve the failure rate ($a = 5$) the result would not be "significant" Significance would only be demonstrable if a were equal to 3 or less, in which case the failure-rate would be reduced to the spectacular figure of 12% or less, and few exponents of insulin therapy would regard such a claim as reasonable Indeed, were insulin that good, it is unlikely that there would be sufficient expert disagreement for a trial to be considered appropriate Even if insulin were to halve the failure rate a trial of twice the size would be about as likely as not to fail to detect a "significant" therapeutic advantage

Conclusions from such analyses of such data on trials of practicable size under conditions which justify a trial (e g, expert disagreement) will almost always be either that there is no difference, or that there is a difference, but that it could easily have been due to chance (i e, it is not "statistically significant")

It is not altogether unfair to term this the heads I-win tails you lose technique of therapeutic trials In diseases in which there is so little to measure or enumerate, it seems very questionable whether such a trial can reveal therapeutic advantages with the precision of the casually acquired beliefs of experienced observers

Although experience is frequently fallacious, judgment is often impossible

Birmingham, 15
J H EDWARDS

UNMARRIED PARENTHOOD

SIR,—Now that we have completed the circuit of the course, may I revive the matter which initiated the correspondence? Dr Hamilton (March 30) makes the critical point of it: every child has the right to be conceived in love, born in happiness, and nurtured in security. A great deal of human coition takes place, and will quite certainly continue to take place, in circumstances which, within marriage or outside it, do not fulfil these conditions. It is possible to ensure that in a proportion of these cases, at least, coition will not be followed by conception. It seems to me that if we are really concerned with the rights of the child, we should attempt to ensure that this is so. If we are not concerned very much about the rights of the child, but very greatly concerned to preserve a particular doctrine of conduct, we shall wish to limit the availability of contraceptive knowledge so that we can continue to appeal to the rights of the child when appeals to the beauty of holiness wear thin. It seems to me that while we may well hold our own conclusions upon the doctrine of conduct, we ought not to let our zeal for it increase the number of unwanted children among those who find our doctrine unconvincing; by withholding contraceptive knowledge in the interests of sacramental marriage, we shall certainly not stop human beings from coition in a very wide range of contexts. By providing it, we might even make more of these contexts sacramental, instead of psychologically and morally negative.

RUPTURE OF THE PREGNANT UTERUS

SIR,—I was most interested in the 3 cases of ruptured uterus reported by Mr Higgins (March 23). His opinion that a change may be appearing in the commoner causes predisposing to uterine rupture is one which I have held myself for some time.

The tragic ætiology of the accident in the past has often been the neglected transverse lie, the unrecognised hydrocephalic, or the unsuspected pelvic contraction in the multipara—abnormalities which are more frequently recognised now and appropriately dealt with before there is any danger. There has always been, however, a group of patients—previously a small group but now relatively much larger—in which no major fault had been present to explain why the uterus ruptured. In this group a weakness of the uterine muscle may have arisen from a cervical tear, or following difficult manual removal of an adherent placenta, or, as Mr Higgins suggests, following traumatic curettage. Such a weakened area might give way during a labour only slightly more difficult than usual, perhaps due to no more than a large child or a degree of extension of the head, two abnormalities which were illustrated by Mr Higgins's first case.

As a further illustration of the changing ætiology of uterine rupture, I would like to quote some figures previously reported.[1] Between 1951 and 1955, in Sheffield, 8 cases of uterine rupture were seen in the Jessop Hospital for Women and the City General Hospital. In only 1 was the rupture due to a neglected transverse lie; in 1 it was due to an attempt to deliver the impacted shoulders of a baby weighing $11\frac{1}{2}$ lb; in 1, to a previous Fothergill colporrhaphy; in 1 to a pregnancy in a rudimentary uterine horn; in 1 to previous fundal perforation during curettage; and in 3 the rupture was unexplained in multiparous patients.

I think that the importance of the changing ætiology lies in the need for us to think of the possible diagnosis of rupture of the uterus under different circumstances than in the past. When signs of shock appear in a patient with obstructed labour due to transverse lie or gross disproportion, the diagnosis of rupture of the uterus can usually be made without difficulty. When, however, collapse occurs without any apparent reason in a seemingly normal labour—or even in pregnancy, as in 2 of Mr Higgins's cases—the suspicion of uterine rupture may not so easily arise in our minds; the absence of the common ætiological agents of the past may delay the correct diagnosis in favour of, say, accidental hæmorrhage or adrenal hæmorrhage, with the result that operation may not be performed in time.

I think Mr Higgins's paper has given us valuable additional information on the present-day ætiology of this serious accident.

OBSTETRIC FLYING-SQUADS

SIR,—Mr Telfer Gray (March 30) should realise that seven years in one mission hospital provides only a parochial picture of a vast problem. I did not visit the Bolobo area, and have no information of the Bayanza or the Wadia whom, I suspect, he served. My safari was to visit personally the authorities upon the subject of my research and the tribal villages of the people over a wide area of the Belgian Congo and Central and East Africa. We do not form our own opinions from a six months' investigation, but we acquire and profit by the expert knowledge of local witnesses.

My statement, that postpartum hæmorrhage is almost entirely absent in uncomplicated labour among unurbanised tribal Africans (March 23), is amply justified by the evidence that I have upon this subject and the status of those who generously gave their time to help me in this investigation. If Mr Gray could study these original documents he would appreciate the limitation of his experience and withdraw his uncalled-for imputation that I imagine Africa to be an obstetric Utopia.

Chichester **GRANTLY DICK-READ**

AN ADJUSTABLE SPLINT FOR FRACTURES INTO THE KNEE-JOINT

SIR,—I was interested to see a modification of my splint by Mr Tupman (March 23). Several similar alterations have already been suggested by other users of this method. When this form of traction and splintage was originally devised and published, it was my deliberate intention to keep the apparatus as simple as possible so that it might be readily assembled from existing materials. I have, moreover, continued to use this method unmodified to my satisfaction since that time, although I agree that there are certain slight disadvantages in the maintenance, to which Mr Tupman refers. Like him, I have found the method particularly valuable in the treatment of injuries in the neighbourhood of the knee-joint, and indeed I know of no other method by which bony union can be quickly obtained with good alignment while preserving an excellent range of knee movement.

I am hoping shortly to publish my own modification of the splint which resembles in some ways Mr Tupman's but over which it has certain advantages—namely, retention of the simple "rigging" and incorporation of a hinge at the knee which adjusts itself to the alteration in the axis of the knee during movement. I still prefer to use skeletal traction through a Steinmann pin in the upper end of the tibia, but I agree that strapping traction is a perfectly satisfactory alternative.

I firmly believe, however, that modifications of the splint are of themselves of little importance compared to the underlying principle involved in its use—namely, early return of synergic muscle action, which promotes rapid bony union and retains a supple and powerful lower limb.

EPIDEMIC VERTIGO

SIR,—Your excellent annotation (March 16) has prompted me to review my own thirteen cases seen over the past 5 years in the southern part of the New Forest, in an area extending from Christchurch to Southampton

There has been at least one case every year, including two so far this year Five were in men and eight in women Three were aged 30–39, one, 40–49, six, 50–59, and three, 60–74 Coryza preceded the illness in four cases, and the onset was fairly evenly distributed throughout the year

Five patients had headache, eight nystagmus (obtained sometimes only in certain positions of the head), one fever, five tinnitus, and one diplopia The blood (leucocyte and differential counts) and the cerebrospinal fluid were normal in the four cases in which these examinations were made An electro-encephalogram in one case showed "minimal non-specific dysrhythmia—insufficient to give opinion"

Promethazine 8 chlorotheophyllinate ('Avomine'), given first at the suggestion of Dr E W Deane, of Christchurch, has been successful in the treatment of three cases and in some further cases treated by Dr Deane

All the patients were widely distributed and none had any known association with another But one reported that her daughter and son-in-law, all living in the same house, had suffered from similar symptoms of shorter duration in the preceding week, and one (a Customs officer) reported similar symptoms in three fellow officers with whom he worked

In five cases there was a relapse after some days of freedom from vertigo

SECRET REMEDIES

SIR,—In his erudite and derisive lecture, to the Royal Society of Arts on Quacks Through the Ages (mentioned on p 223 of your issue of Jan 26), Mr Dickson Wright defined a quack as "one who sells a secret remedy" Some such remain among us, who blend a variety of pigments with their pills, dispensed as triplets, anonymous and unobtainable by prescription to patients or family doctor On a different plane, there is still, even in conventional practice, a tendency to cover the label on prescribed proprietary preparations, which practice might well be relegated to a past era of mystery and mysticism in medicine I recognise that this would make it more difficult to satisfy the patient who travelled several thousand miles to this country to receive the same treatment as had been successful with his friend and which, he thought, was called "placebo"

London, W 1

S LEONARD SIMPSON

A MISSED FRACTURE

SIR,—I cannot agree with Dr. Stone (Feb 2) that a coroner has "no power to criticise anyone" Coroners have always reserved to themselves the right to criticise those whose negligence or lack of foresight has contributed, however slightly, to the death under investigation Nor do I endorse his final opinion that the public has no right to expect "completeness"—perhaps "thoroughness" would have been a happier word—in the examination and treatment of patients referred by their own doctors to the casualty department of a general hospital

When an elderly person falls sufficiently heavily to break an arm, the possibility of a concomitant fracture of hip or femur should never be overlooked I think the coroner was perfectly justified in directing his criticism towards the casualty officer concerned The family doctor's duty ended when he recognised the need of hospital treatment for his patient, and the casualty officer's duty surely includes the elimination of likely complications—which do not embrace "a host of other possibilities" such as diabetes mellitus or carcinoma of the sigmoid colon Had the old lady, in fact, died from any such condition the coroner would not have seen fit to offer any criticism at all Dr Stone's indignation is, I feel, misdirected, and his closing remark something of a non sequitur

Komani Hospital,
Queenstown, Cape Province

R DINGWALL KENNEDY

CARDIAC ARREST

SIR,—The recent report by Bencini and Parola of the efficacy of pneumomassage in maintaining the circulation despite cardiac arrest[1] recalls some speculations that several of us indulged in some years ago

Deterred by technical considerations from attempting massage by intermittent pressure within the pericardial sac, we considered the effect on the circulation of intermittent pressures within the thoracic cavity We know that forced respiratory movements against the resistance of a closed glottis, or of a mercury manometer, can raise the intrathoracic pressure to nearly 100 mm Hg Of course intra abdominal pressure is also raised to the same degree, and this pressure tends to propel blood away from the heart, towards the head and extremities, in the great veins as well as the arteries Such pressure might be expected to empty the entire left heart Possibly such intermittent forced expiratory movements against resistance could maintain some cerebral circulation, in a manner analogous to electrophrenic respiration

The experiment we envisaged consisted in supporting the chest and abdomen of the animal whose heart was stopped, with either a close fitting (possibly pressurised) cuirass or tight bindings, while applying intermittent pressures of about 150 mm. Hg to a tight fitting endotracheal tube at a rate of about 120 per minute, and recording arterial and venous pressures in the neck or thigh

So far as we know this has not yet been tried

Livernois Clinic
Detroit 10 Michigan, U S A

SAM I LERMAN

PENICILLIN IN THE TREATMENT OF LACTATIONAL BREAST ABSCESS

SIR,—Dr De Jode's article (March 16) confuses an already difficult situation I refer to the respective values of penicillin therapy for severe staphylococcal infection, in hospital and in domiciliary practice

Many workers are aware of the limitations of such therapy within the hospital environment, but observant general practitioners remain pleasurably surprised at the continued success of this drug in their practice More recently, articles dealing with the subject of staphylococcal ecology show that the success or failure of the treatment is largely dependent upon the source of infection, and many general practitioners are well aware of this

Surprisingly, Dr De Jode does not comment on his finding that 71% of breast abscesses occurring in mothers confined at home were due to penicillin-insensitive staphylococci Epidemiological studies show that the frequency of penicillin resistant staphylococcal infection runs pari passu with the extent of the nasal carriage of resistant strains of the causal organism In this part of the world 10–25% of the general population carry in their noses penicillin resistant staphylococci, whereas large hospital communities show a frequency which varies between 50 and 70% It is therefore reasonable to assume that Dr De Jode's group of "home confinements" is not representative of the general population, or that the bacteriology of these cases requires further elucidation It would be useful to know, for instance, by which method the in-vitro sensitivities were determined.

Dr De Jode suggests that it is reasonable to restrict the use of penicillin to those cases of breast abscess following home confinements—with 71% penicillin resistance—where "there is therefore a reasonable chance of dealing with an organism sensitive to penicillin," thus illustrating the uncertainty of conclusions drawn from records of this kind Perhaps it would have been more useful to emphasise the fact that, in this series of cases, the average duration of penicillin therapy was only $3^1/_2$ days

H G SMYLIE

VITAMIN B_{12} IN PSORIASIS

SIR,—Several reports have been published recently on the efficacy of vitamin B_{12} in certain skin diseases and particularly in psoriasis Muscardin[1] has treated 31 patients with psoriasis and reports that a dose of 1000 µg daily for ten to twelve days produced an "excellent" result in 7 patients, and "good" results in 12, and on the whole those patients who had itching were helped most

We have used vitamin B_{12} in these doses for ten days on 12 patients suffering from psoriasis The first patient treated, in an acute and exfoliative stage, did improve rapidly Five months later, however, the same patient had an exactly similar episode, and the vitamin B_{12} seemed to have no appreciable effect, though given in the same dose for the same length of time

The other 11 patients treated were "paired" with patients suffering from the same type of psoriasis, one group was given vitamin B_{12} and tar ointment, the other group tar ointment only No appreciable difference was noted, either in speed of recovery or in well being, in the two groups

My thanks are due to Dr Alice Carleton who permitted me to treat the patients

Oxford.

SUZANNE ALEXANDER

CYTOLOGICAL DETECTION OF UTERINE CANCER

SIR,—I am sorry to see you have once more launched into the common confusion and arguments about the "true value" of cytological detection of uterine cancer The last time you did this[2] both Dr Osborn and myself were moved to protest Last April[3] I was content to see you on the right lines at last when you opened another leader with the sentence "Incredulity has delayed the development of exfoliative cytology in this country" Your leader of March 23 still bristles with misunderstandings, some of which I hope you will allow me to help to clear up

The main reason, you say, for views differing on the value of the method is that many reports do not make it clear how often cytology has really helped to make a diagnosis I agree that too many reports are presented with a final "percentage accuracy," which has already been exploded by Howard Taylor, jun, of New York, as meaningless, but our Edinburgh reports have been based *solely* on how often cytology has helped, and our last published total was of 9910 cases of gynaecological outpatients, screened by gynaecologists, with 98 cases discovered which would otherwise have been missed[4] Our series from a contraceptive clinic and from general practitioners is excluded Only two-thirds of these were cancers in situ, and the remaining third were invasive growths No cases of clinically obvious cancers were included in these numbers as cytology cannot accelerate their diagnosis

When we have been in doubt as to whether we have "surprised" the gynaecologist with a positive report, we have asked him and during our earlier years we had access to his letters to the practitioners who referred cases in the first place and this told us whether he suspected the cervix or not, where it was not otherwise clear When, as has occurred, two senior gynaecologists disagreed about the naked eye appearance of the cervix, the case has not been counted When, as has occurred, a senior gynaecologist has described a cervix as "looking benign, but should have biopsy," who should say whether he has been suspicious or not? This question of "clinical suspicion" seems to be the crux of the difference between the Birmingham and Edinburgh figures You state "it was not certain that [the Edinburgh] patients had always been subjected to as searching a clinical inquiry as those of McLaren et al" I can relieve this uncertainty by stating quite confidently that *none* of our patients was subjected to as searching a clinical inquiry and questionnaire

We have in fact been treated to descriptions of cervices on many occasions which show that the clinician is trying to have it both ways, and we realised before our first report, in 1951,[5] that correlation of our results with clinical suspicion was too dependent on subjective impressions for useful assessment—even when dealing with the most experienced gynaecologists, as the degree of suspicion is too easily influenced by the history

Dr Bamforth,[6] at the meeting (quoted in your leader) at the Royal Society of Medicine in November, 1955, stated that by "unsuspected" is meant "no biopsy would have been taken except for the positive report on the vaginal smear" This is excellent, though it is better still to include the gynaecologist's opinion of the cervix The appearance of the cervix on speculum examination must come into the question of clinical suspicion McLaren,[7] at the same meeting, was anxious for a definition of the "surprise" discovery of an unsuspected case, mentioning the symptom of post coital bleeding as being very important The implication is that the cervix looks different if the beholder knows the patient has had post coital bleeding In the *management* of a case he is right, for an erosion of the cervix associated with leucorrhœa in a girl of 25, is cauterised without further ado by most gynaecologists, whereas the same appearance in a woman of 55 with post coital bleeding, naturally gives rise to clinical suspicion We believe that "clinical suspicion" is too subjective to be the sole criterion of assessing the method, whose "true value," if there be such a thing, may be entirely personal to one or other group of gynaecologists It would be interesting to know, in McLaren's series, how often clinical suspicion proved groundless, yet led to hospital admission, anæsthetics, biopsies, and curettage

In parenthesis, although Dr Bamforth has a definition for the unsuspected cervical cancer, he later refers to Wachtel's 7 "unsuspected" cases of carcinoma of the uterus, without any definition What is an unsuspected case of body carcinoma? Surely only the pre menopausal cases? Are we not properly trained to suspect every case of post menopausal bleeding with a healthy cervix as a possible body carcinoma in need of urgent diagnostic curettage?

Your last paragraph makes a practising gynaecologist and cytologist feel very old It is acknowledged, and always has been, that the method must never become a substitute for clinical investigation I would assert that no cytologist or pathologist has ever claimed that it could, or should, but clinicians would often like to take short cuts, and this advice should be directed to them In cases of clinical suspicion, with negative cytology, our reports repeatedly warn the clinician to ignore the cytology report, and investigate along traditional lines

In spite of McLaren's expression of perplexity and your own query as to the "true value" of the method, he gave the only answer himself when he called it "a laboratory test of considerable importance" We will progress further if we leave it at that and get on with it There is no doubt whatever that the method has come to stay in spite of all the self torturing of those with the time for elaborate questionnaires The method is not, and in this country never has been, "research," for it was well established in America before it was started in Britain, but it can be used for investigation of the natural history of cancer, once it has been learnt, which is a different matter

Edinburgh

INFUSION NEEDLES

SIR,—As a house surgeon whose patients specialise in small veins and whose "drips" occasionally exhibit a poor sense of occasion, in not knowing when not to stop, I would prefer a smaller needle for use with the giving set

Even a makeshift syringe needle, when used for the same purpose, seems less likely to cause thrombosis, and the standard giving set needle is cruelly oversize, except perhaps for giving blood

DAVID FURNISS

St James s Hospital
Leeds 9

PEDICULOSIS CAPITIS

SIR —In their article of Feb 23, Dr Nelson and Mr Cromie refer to reinfestation taking place mainly in the family circle It would be interesting to have details of the treatment given to these cases in the first instance

It is commonly supposed that preparations such as dicophane application *B.P C* need only be left in contact with the hair for 24 hours, in fact the directions given in the *National Formulary* include the sentence "Do not wash the hair during the next 24 hours" This is too short a period and at least 7 days contact should be allowed None of the residual insecticides is effective against nits and it is only by allowing time for the nymphs to hatch and come into contact with the insecticide that a complete kill can be ensured

Our experience in the Army is summed up in the following passage from the *Manual of Army Health*, 1954

> "The most efficient method of treating head lice is to apply a persistent insecticide and leave it there for a week, the hair should not be washed during this period"

London S W 1

REACTIONS AFTER TRANSFUSION

SIR,—In a leading article in 1955[1] you noted that 1–2% of all patients transfused with blood were liable to reactions other than those due to mistakes in blood-grouping or cross-matching techniques You added that 1–2% of recipients had urticarial and other allergic reactions, while 2–5% had febrile reactions, and you remarked that different workers had sought in various ways to reduce the frequency of the reactions, either by sedation or by giving an anti-histamine The choice of anti-histamine and the mode of administration are still undecided Since reading your leader, I have always advised that patients to be transfused, other than under a general anæsthetic, be given a sedative and oral anti histamine, the choice of drugs used being governed by the wishes of the clinician concerned The routine technique for all cross matches performed under my direction has included the use of a saline and albumin technique at room temperature, as well as saline, albumin, and indirect anti-globulin techniques at 37°C Moreover, a smear of the blood to be given has always been stained with methylene blue and examined microscopically to exclude any possible infection of the bottle concerned

Over a period during which 2295 pints of blood were administered, 16 patients had rigors, 4 pyrexial reactions of over 100°F and 2 urticaria Checks of the group, the cross match tests and the possibility of infection or hæmolysis in the bottle of blood on return to the laboratory were all invariably negative 2 patients, both treated at the beginning of the period under review, had had two reactions at the commencement of a transfusion, despite the transfusion of fresh blood, sedation, and the administration of an anti histamine It was decided to treat these patients with chlorpheniramine maleate, 10 mg to be introduced into each bottle immediately before use This technique enabled us to transfuse these cases repeatedly (3 times and 4 times respectively) without further incident It was decided thereafter to transfuse all patients who had previously had a transfusion reaction in the same way, having excluded any possibility of blood-group incompatibility It should be emphasised that this use of chlorpheniramine maleate was reserved only for those who had had such transfusion reactions

During the period under consideration, 90 bottles of blood containing chlorpheniramine maleate were administered, and of these 88 were accompanied by a perfectly uneventful course, with no sign of reaction whatever The other 2 produced febrile reactions of 99 8°F and 100 2°F respectively, but neither patient had a rigor The first patient was not again transfused, and the second, after 2 transfusions of washed red cells in saline, which gave no reaction, was later successfully transfused with whole blood, again accompanied by chlorpheniramine maleate

While this small series cannot pretend to be anything more than a limited examination of the problem, it nevertheless suggests that chlorpheniramine maleate can make it possible to transfuse patients who might otherwise prove resistant to such therapy Such results are in accordance with those of Simon and others[2–7]

I am grateful to the clinicians of Westminster Hospital for their most helpful coöperation in collecting this series, as well as to Messrs Allen & Hanburys for the provision of chlorpheniramine maleate in the form of 'Piriton Maleate' 10 mg ampoules

PHENYLBUTAZONE IN SUPERFICIAL PHLEBITIS

SIR,—I should like to draw attention to the remarkable effect of phenylbutazone in cases of superficial thrombophlebitis In a series of 23 cases results have been highly gratifying, and it has been possible to reduce very considerably the length of the illness

The patients treated can be divided into two groups

15 patients had acute superficial phlebitis without ulceration The effect of phenylbutazone in these cases was dramatic Pain relief was quickly obtained, and inflammation subsided rapidly All cases cleared up within five days, and patients were ambulant soon after treatment began

8 patients were subject to periodic mild attacks of superficial thrombophlebitis, leading to shallow but painful ulceration of the leg Such cases previously took four to six weeks to heal, but with phenylbutazone they cleared up within ten days

This series is admittedly not large enough for statistical comparison with similar cases admitted to hospital for conservative treatment, but the results are so striking that I feel they should be made known at once A wider trial seems highly desirable

GOVERNMENT AND PROFESSION

SIR,—In his letter last week, my neighbour, Dr John Fry, deplores the manner in which the profession's claim has been presented I agree that the claim should have been associated with an expressed desire to examine defects in the existing service He does not, however, stress sufficiently the fundamental defect in the scheme from which the present weaknesses spring, nor do the remedies he suggests all appear pertinent to the issue

The defects arise, as far as general practitioners are concerned, from the fact that the majority are attempting, valiantly if inadequately, to stretch old conditions of practice to meet the demands of a new age—an age that is characterised by an increased understanding of the individual in health and disease together with a changed sociological outlook that demands the national application of this knowledge The family doctor's increased area of responsibility is indicated by the widely varying demands for advice made by his patients He daily dispenses pædiatric guidance, support for the adult neurotic, care for the aged, some measure of health instruction, in addition to his constant therapeutic attack on established disease Obstetric management has moved far beyond the immediate demands of a successful confinement The single handed practitioner must rarely succeed in providing this comprehensive service His difficulties are lack of time and often inadequate facilities, together with insufficient auxiliary help

The basic need seems to me, therefore, to be that of stimulating group practice, not merely in the sense of multiple partnerships but in that of a coordinated effort with each of the group accepting special responsibilities With this should go the organisation of suitable premises and the employment of ancillary help

Financial injections should not therefore be aimed at keeping alive outmoded conditions The suggestion that a system of "merit awards" would promote a more desirable practice organisation will not "meet the bill" Sheer lack of cash would prevent the young practitioner, and for that matter most single-handed doctors, however enthusiastic, from qualifying for such an award If incentives to joint practice were coupled with a mode of remuneration that paid adequate regard to the expense factor and thus promoted capital investment, good practice would be furthered Among other benefits might be the disappearance of what is surely an anomaly—the "assistant without a view"

The suggestion that periodic examinations throughout life be stimulated by additional payments is surely of limited value It would promote a niggardly approach to, say, pædiatric and geriatric care Where a practice is known to provide, for example, a satisfactory pædiatric clinic, then much more will be accomplished in the way of supervision during childhood than by periodic examinations Not only would the early detection of disease be forwarded, not only would some degree of health instruction be provided, but the chance created to influence the emotional climate in the home where this is needed Similarly, given adequate practice organisation, proper supervision could be maintained throughout life It is surely the continuity of contact with his patient that is the general practitioner's special asset

Local health authority clinics must inevitably disappear with the extended care undertaken by the improved organisation of practice This would release the various local authority auxiliary services for their better employment by the G P The one feature of the school health service that seems to be valuable and should be retained is the advice given by the examining doctor to the individual school head This should prove, however, no great administrative hazard

If specific efforts are to be stimulated by extra fees then the most pertinent one appears to me to be that already suggested in your editorial columns—namely, the domiciliary care of the acute sick

My theme, therefore, is that, given the right conditions of practice, current weaknesses will tend to disappear Even if there is no general support for this approach, surely we can agree that publicity should be given to the profession's good will towards the N H S and, as an earnest of this good will, to our desire to examine and remedy its defects

Beckenham, Kent. D I FINER

SIR,—How right Mr Patey is to suggest, in his letter of March 23, that it is time that discussions between the doctors and the Government should include matters other than salaries However, I cannot agree that granting to patients who consult their doctor outside the National Health Service the right to N H S prescriptions is a desirable reform Surely the most important matter for the doctors to discuss with the Government is how to reduce the bill for prescriptions on the N H S, which during the past year has increased by £5 million If some way could be found to eliminate prescriptions for medicines which could not conceivably do any good to the patient, enormous sums of money would be saved and the doctors should deservedly get a rise out of the savings

Unnecessary prescribing arises because the patient has grown to expect a prescription, and the doctor feels obliged to fulfil the patient's expectations The remedies are *twofold* First, the general practitioners must be courageous and tell the patients the truth They might be encouraged to do this if their salaries were made more independent of the number of patients on their books Secondly, an attempt must be made to reduce the demands of patients I suggest, as a start, that a meeting be called of the editors of all journals that publish sections on health and beauty The editors' attention should be drawn to the undesirability of encouraging readers to make self-diagnoses and then demand the latest drug from their doctors The Radio Doctors must have done untold good to the anti-medicine cause in their time

London, N 12 PETER N CAMPBELL

SIR,—As one who has always liked general practice and who has always held that the general practitioner could conform to the highest standards of *family* medicine, I find your leaders on the proposed withdrawal, to secure justice for ourselves and for the standards of practice, at once biased and inaccurate *Findings* such as these, if true, are a sorry condemnation of your journal, which should surely uphold the standards of general practice if not the just remuneration of the practitioners responsible for the maintenance of such standards

We are not planning a strike The word denotes a *total cessation* of work, whereas we unanimously intend to care for our patients as before, but under different financial and administrative arrangements

We are not using politics or political force We are opting out of the N H S because our employers consistently refused to recognise the Spens and Danckwerts judgments, just as their predecessors had done

Unlike the striking artisans, we are mainly concerned with securing such additional monies as will pay our vastly increased practice expenses and enable us at the same time to improve our medical service to the community

Your underlying implication that we are lowering our medical traditions and social esteem is bitterly resented inasmuch as its manifest untruth will not prevent some splitting of our professional ranks nor some bolstering up of the present Government In fact, your leader last week is itself a potential political weapon and in no way a help in the maintenance of medical traditions and standards or efficient care of the community

Manchester J G O'SULLIVAN

SIR,—Few can be feeling happy about the outcome of the B M A 's present plan for a doctors' "strike" A better idea would be to pull out the key men at a bottleneck—the teachers of and examiners in anatomy and physiology There are so few of these that the rest of the profession could afford to subsidise them indefinitely

This would take a few years to work but in the end the pressure would be irresistible In the meantime, it would have the advantage of diverting some thousands of young men and women from an overcrowded profession, where they are *not* wanted, to more useful occupations

Clifton Bristol, 8 GEORGE L ALEXANDER

Parliament

Nuclear Hazards

In the course of his report on the Bermuda talks to the House of Commons on April 1, the Prime Minister said that nuclear power was the basis on which Britain's defence plans must at present rest The only question that remained therefore was whether the process should be brought to fruition or whether we were to hesitate at the last stage when the necessary tests had to be made before production was carried out He recognised that the Opposition asked him to abandon the tests from sincere and conscientious motives, but did they accept the logical consequences of abandoning the weapon ? This, he said, would mean permanency of conscription and the need to raise far larger armies

Turning more particularly to the question of limiting the tests he said that late in December Sir Anthony Eden had been working on proposals to limit the tests even outside a general disarmament agreement, but he had to tell the House that a simple agreement, such as the Government then had in mind, as to the permissible yield of fissionable material without any detailed arrangements for control would not work The scientist was always ahead of the politician What might have seemed possible some months ago was now confirmed as not being watertight The proposals were based on the assumption that the total yield of the explosion was a reasonable measure of the fission products discharged into the atmosphere It was now clear that that was not necessarily the case He was assured by our own scientists as well as by the Americans that there was no feasible method of properly measuring at a distance how much of the yield of a particular explosion was due to fission and how much was due to fusion Our scientists believed that a deliberate attempt to run a test explosion in such a way as to avoid detection would almost certainly be successful So far as we knew, no such attempt had been made On the other hand, there had been instances in which our scientists were unable to be certain whether an explosion had taken place or not For these reasons they had agreed at Bermuda that the original approach would not do But it would be an error to say that the Bermuda communiqué once more attached the concept of test-limitation to a comprehensive disarmament agreement It said that it must be accompanied by general nuclear control Such a system would at least have to include watertight measures of policing any test-limitations which might be agreed upon The President and he had agreed to go a step further while waiting for any general agreement They said that they would " conduct nuclear tests only in such manner as will keep world radiation from rising to more than a small fraction of the levels that might be hazardous "

So far as our own tests were concerned he had been asked to say that there would be no perceptible radiation outside the test area He was satisfied from the medical and biological point of view that the radiation effect of this explosion would be insignificant

The closest watch was being kept on possible dangers to human health and we had regular and up-to-date measurements External radiation, which constituted the main genetic hazard, was not in any sense a new kind of hazard, and, only a small proportion of it was attributable to bomb tests Natural sources of radiation, were estimated to give an average dose of $^{1}/_{10}$ roentgen a year, or 3 roentgens during the thirty years of an average reproductive life Modern civilised man had added by his own inventions, to the amount of dosage received in a normal lifetime, and especially in recent years These included X rays, and such things as luminous watches, and the development of atomic energy in industry All these new man-made sources of radiation gave us an additional dosage which, in this country, was reckoned to add at least a quarter to the 3 roentgens we already received from the natural background Unless, therefore, we were prepared to abandon X rays in medical treatment and many other features of our civilisation, we must expect to be exposed to about 3$^{3}/_{4}$ roentgens each every thirty years

It was estimated that, if test explosions go on at the same rate as in the past few years, in the course of a long time the external radiation from fallout would build up to an exposure per generation of not more than $^{1}/_{100}$ part of what man would receive in the same period from natural sources alone To this $^{1}/_{100}$ of the 3 units, which was the most from the explosions up to now, the explosions we proposed to make shortly could add not more than a small fraction of the total explosions already made by Russia and the United States

Apart from the external radiation to which bomb-tests made a very small contribution, there was the internal radiation due to the absorption into the body from food or drink of substances such as strontium 90 which were part of the fallout It was fair to say that the average levels of strontium 90 at present measured in human bone in the United Kingdom were less than 1 unit and that was 100 times less than what, in the view of the Medical Research Council, was the maximum allowable concentration in bodies of individuals of the population

The Government took this matter very seriously They would keep it under continuous review in the light of any new advance, both in this country and elsewhere But he believed that we should add very little to this danger by the test we were about to make and we should gain enormously in strength and in the defence of our country

Other aspects of this problem were raised at Question Time The questions included the following

Dr Barnett Stross asked the Minister of Health by how much the expectation of life was reduced as a result of exposure for ten years to the maximum permissible ionising radiation to which workers in radioactive substances may be exposed —Mr Dennis Vosper replied There is very little evidence regarding the possibility that exposure to radiation may affect the expectation of life in man, and it is therefore impossible to estimate the effect in this respect of any particular dose The present recommended maximum permissible levels have been chosen as providing a substantial margin of safety below the minimum dose known to produce any effect Dr Stross Is it not suspected, however, that 10 or 15 years' work at the maximum permitted dose would reduce the expectation of life by about 18 months ?—Mr Vosper There is a great variety of medical opinion about this I would not wish to accept that estimate as being the correct one It could well be less

Dr Stross asked the Minister whether he was aware that ground bone meal was used as an ingredient in some food for children and invalids , and what research was being conducted on the presence of radioactive strontium in cattle whose bones are so used —Mr Vosper replied I understand that treated bone meal is used in very small quantities in some cereal foods mainly intended for infants No measurements of the level of strontium 90 in cattle bones have been carried out in this country but there is evidence that the levels are comparable to those in milk Dr Stross In view of the fact that strontium is taken up in bone just as calcium is taken up in bone, is it not desirable that ground bone should not be used in any food for invalids and infants unless we know exactly whether it is safe or not ? Is the Minister not aware that the bones of sheep, in Wales in particular, are said to be very highly contaminated with radioactive strontium ?—Mr Vosper Watch is being kept on this matter mainly in connection with the effect on milk I am sure that the Medical Research Council is concerned about this and that advice will be given if necessary

Mr Somerville Hastings asked the Minister whether he would inquire of the Medical Research Council to what extent the thermonuclear bombs so far exploded had resulted in a tendency to increase mutations and, in consequence, the number of deformities in the human race during the next 1000 years —Mr Vosper replied I am advised that, while all radiation does affect human mutation rates, our present knowledge of the subject shows that compared with the radiation to which man is already exposed, the additional amount which has been produced by the thermonuclear bombs so far exploded is so small that the genetic effects would be insignificant Mr Hastings Does the Minister realise that scientific opinion is changing very rapidly in this direction ? Has his attention been called to a report on the genetic effects of radiation by the World Health Organisation, from the Press release of which I quote as follows

> " all man made radiation must be regarded as harmful to man from the genetic point of view "

Whilst the harm may not be very great, at any rate as we see it at present, is it not perfectly clear that harm is bound to follow ?—Mr VOSPER The hon Member asked me to inquire of the Medical Research Council, and he will know that the committee, in its report last year referred to the fact that an increase of only 1% of that from normal sources could be expected From my further inquiries, I understand that that estimate is still reasonably accurate Dr SUMMERSKILL Is the Minister satisfied in always quoting from the report of June 1956, in view of the fact that this committee was convened in 1955 and Professor Haddow himself has been making public statements that there has now been a shift in emphasis since June, 1956 ?—Mr VOSPER I thought I had made that clear I have made inquiries of the Council as to its present attitude, and it confirms that the report still holds good

QUESTION TIME

Remuneration

Mr ARTHUR BLENKINSOP asked the Prime Minister whether he would make a statement on the form of any interim award to general practitioners in the National Health Service pending the longer term review being undertaken by the Royal Commission —THE PRIME MINISTER I have nothing to add to the reply I gave on March 19

Mr BLENKINSOP May I ask whether the right hon Gentleman would not now make some suggestion to clarify the statement which he himself made in his letter ? Does he not realise that no one in the House supports the point of view expressed by the doctors, who so far are refusing to submit evidence to the commission ?—THE PRIME MINISTER I can only say that I hope to make a statement shortly

Mr HENRY HYND asked the Minister of Health what arrangements were now being made to deal with the situation which would be created by the proposed withdrawal of doctors from the National Health Service —Mr VOSPER At the moment, I do not wish to add anything to the statement made by the Prime Minister on March 12 Mr HYND Is it not very desirable, in view of the serious effects which will arise if this dispute is allowed to develop, that something should be prepared now to meet that contingency ?—Mr VOSPER I have read that it is suggested that doctors may withdraw from the National Health Service on Oct 2 My right hon Friend said that he would make a further statement in due course, and the hon Gentleman could deduce that that would probably be before Oct 2

Mr K ROBINSON Would the Minister convey to the leading members of the medical profession that this suggestion in the view of most people, including many who are sympathetic to the doctors' claims, is both irresponsible and ridiculous ?

Leukæmia

Mr BLENKINSOP asked the Minister to what extent there had been an increase in deaths from leukæmia over the past 30 years —Mr VOSPER replied In 1923 the number of deaths certified as due to leukæmia (including aleukæmia) was 552 representing a death rate of 14 per million persons living In 1955 the number of deaths was 2224 and the rate 50 per million Mr BLENKINSOP In view of the serious increase which is taking place and the anxieties there are about the possible future growth of this disease, does the right hon Gentleman accept responsibility for giving advice to the Prime Minister about the possible effects of future hydrogen bomb tests, in view of the clear indication that these tests, on whatever scale, are bound to have an effect upon the strontium of the body ?—Mr VOSPER I think the hon Member should not come to too rapid conclusions A great part of this increase took place in the years 1925–45 There are a number of causes contributing to the increase Of course, the matter is very much in my mind and in that of my right hon Friend

Mr B HARRISON Would the Minister make sure that the most modern equipment is available for X ray photography and that this photography is not a cause of the increase in leukæmia ?—Mr VOSPER I think it may well be a cause, and it is, in fact, being investigated by the committee under the chairmanship of Lord Adrian

Merit Awards

Mr J W W PEYTON asked the Minister on what basis merit awards were made to consultants, by whom such awards were recommended, and to what extent regional hospital boards who had to meet the cost were consulted —Mr VOSPER replied Awards are made for professional distinction and on the basis that 4% of consultants receive awards at the rate of £2500 a year, 10% awards at the rate of £1500 a year, and 20% awards at the rate of £500 a year The recommendations are made by the Advisory Committee on Distinction Awards In view of the basis of the committee's recommendations, regional hospital boards are not consulted upon them Mr PEYTON Does not the Minister feel that there is considerable need for wider knowledge of how this committee makes its awards ? When the award is a continuing one, does it not involve considerable uncertainty among consultants and the medical profession generally ?—Mr VOSPER I am aware that some concern has been expressed about this matter before As I understand it, the whole idea of the awards is that they are on a professional basis

Mrs BRADDOCK Is the Minister aware that, in the early stages of this scheme of merit awards, the details of those who obtained them used to be submitted to the management committees of hospitals, and that that has ceased to be done ? Is it not a fact that at no time are the names of those who receive merit awards submitted to or known to the hospitals in which they are employed ? Will he reconsider the position to see whether it is not wise to start reissuing the names of those who receive merit awards to the hospital management committees concerned ?—Mr VOSPER It is several years since the names were disclosed I understand that the change was made in the interests of patients and not necessarily of the consultants concerned Of course, I will look at it again, but I think the disadvantages would outweigh the advantages

Medical Officers of Health

Mr R S RUSSELL asked the Minister whether he had yet reached a decision on the recommendation of the Guillebaud Committee that the medical officer of health, or one of his staff, should be given an honorary appointment on the medical staff of a hospital , that he should be a member of the medical staff committee , and that he should take charge of outbreaks of infection —Mr VOSPER replied After consulting the bodies chiefly interested, I have decided not to adopt this recommendation Hospital authorities have already been advised of the desirability of medical officers of health being members of group hospital medical committees, and of medical officers of health of sanitary districts being members of control of infection committees at hospitals In my view, arrangements of this kind contribute more satisfactorily to the link between the different parts of the health service which the committee had in mind than formal appointments as they proposed

Lung Cancer and Diesel-engine Fumes

Mr G WILSON asked the Minister to what extent continuing investigation indicated that diesel fumes are responsible for the increasing incidence of lung cancer —Mr VOSPER replied The investigations being made under the auspices of the Medical Research Council into the nature and effects of the exhaust products of diesel engines have provided no evidence to support the suggestion that these fumes are a cause of cancer I hope this statement will remove any misunderstanding which may have arisen as the result of a reply which I gave to a supplementary question on Feb 4[1]

Bath's Mineral Waters

The MINISTER OF HEALTH, in answer to a question, said that the content of the mineral waters at Bath was known and there was no evidence that it would be harmful in pregnancy

Dental Courses

In 1956, of dental courses given under the National Health Service in England and Wales, 41 6% were for patients under twenty one and 1 4% for expectant and nursing mothers

Blood Donations

In England and Wales during 1956 the number of blood donations was 803 522 compared with 759 571 in 1955

---

Obituary

FRANCIS CYRIL OLIPHANT VALENTINE

F R C P.

After a short illness, Frank Valentine died on March 27 at the London Hospital Except during the war, nearly all his work in bacteriology and chemotherapy was done there, and it was done in the best tradition of London Hospital pathology His gently spoken opinions carried much weight, and he will be remembered, too, with much affection

Born in Dundee in 1897, he was at Winchester from 1911 to 1916 He then held an Artillery commission until the beginning of 1919 when he went to Magdalene College as a scholar Both at Cambridge and at The London he showed exceptional ability, and in the natural course of events he became house-physician to the medical unit, first under Charles Miller and then under Prof Arthur Ellis Two qualities which impressed his friends even at this stage of his career were his care in everything he undertook and his sympathy with his patients But he did not like "dealing with" people, and probably he did not really enjoy medicine, except on its scientific side, till in 1925 he took a post in the pathology department as an assistant to H M Turnbull In 1926 he spent a year at the hospital of the Rockefeller Institute in New York, where he worked with Prof T M Rivers on the influenza group of bacilli, and on his return to the London Hospital he joined Philip Panton in the clinical laboratories

When I went to the London Hospital in 1926, writes S P B, Frank Valentine was at the beginning of his career as a specialist in pathology Deriving his inspiration from Panton in all probability, he found greater interest in the application of pathology to the diagnosis and treatment of disease than in the study of its more academic aspects He had set himself to become what for want of a better term we call a clinical pathologist and he was a member of the staff of the clinical laboratory It was to this department that I went as a Freedom research fellow, and I soon learned that he was not only a delightful and cultured person but possessed a keen intelligence and an inquiring mind, discussion of my research problems with him was most profitable Later when, on the retirement of G T Western, Valentine took charge of what was then known as the inoculation department, he and I became more closely associated By then I had succeeded Bulloch in the chair of bacteriology, and traditionally the two departments were linked

But it was during the war that I first learned fully to appreciate Valentine at his real worth He had been put in charge of one of the emergency laboratories in the London Hospital sector, and when Panton went to the Ministry of Health and I took over his duties as sector pathologist I paid regular visits to Valentine's laboratory at Claybury Hospital I was greatly impressed by his quiet efficiency, his skill in improvisation, and the breadth of his knowledge And much of this knowledge was the outcome of his own experience not just what he had learnt by reading For me those visits were both a pleasure and an education

After the war Valentine returned to The London to become director of the department of chemotherapy, and later a university reader in that subject This did not really represent any fundamental change in his work it merely recognised the change of emphasis from immunotherapy and prophylaxis to chemotherapy which, from the discovery of the sulphonamides, had taken place over the war years As a member of the staff of Professor Bedson's department he took his share in the teaching of microbiology, with advantage to the students and pleasure to himself And he continued with his investigations which from before the war had been particularly concerned with the staphylococcus and its role in disease The last of his papers to be published in this journal was a study of the survival of bacterial species under bacteriostasis, and, though some were academic in that they were an end in themselves, the majority had the welfare of the patient as their principal objective In 1954 he was responsible, with Dr R A Shooter, for the third edition of *Recent Advances in Chemotherapy* (vol III) and it was characteristic that he not only checked every fact in his section of the book but undertook special experiments to make sure that the information was completely reliable With the increase in the number of chemotherapeutic agents available to clinicians, he was drawn more and more back into clinical work, and his helpfulness and sympathy made him one of the best loved members of The London's staff As one of his friends there says, "people are inclined to underestimate the importance of quiet unaggressive colleagues who are without malice and maintain in the background a standard of honesty in personal relationships not attained by all of us Frank had this sort of influence at The London" Away from work, he fished in Scotland and played bridge and golf, winning the founder's cup at Sunningdale in 1937 from a handicap of 9

In 1931 Dr Valentine married Freda, daughter of the 8th Earl of Lanesborough She survives him with two sons

GEORGE FREDERIC STRONG

M D Minn, F R C.P, F R C P (C), F R A C.P, F A C P

Dr Strong, professor of clinical medicine in the University of British Columbia, Vancouver, died on Feb 26 in Montreal, where he had gone to preside over a meeting of the National Heart Foundation He was a past president of the American College of Physicians

He was born in 1897 of Canadian parents at St Paul, Minnesota, and he was educated at the University of Minnesota, graduating M D in 1921 A year of his training was spent at the Vancouver General Hospital and he decided to settle in that city In 1926 he was appointed to the staff of the Vancouver General Hospital He was for many years director of the heart station of the hospital and it was as a cardiologist that he was best known, but he had also published a 25-year study of carcinoma of the liver and he was keenly interested in reablement

He had played an important part in the founding of the University of British Columbia, and it was appropriate that he was invited, in 1951, to become its first professor of clinical medicine He was also the first Canadian to become president of the American College of Physicians, holding office from 1955 to 1956 He was an honorary graduate of the universities of Laval, British Columbia, and Toronto and a fellow of the Royal Colleges of Physicians of London and of Australasia

D P writes

In Vancouver Strong was a leader in all things medical He fostered and launched the Western Rehabilitation Centre, one of the best equipped centres for the treatment of post-poliomyelitis and paraplegic cases on the Continent He was able to raise money for such a project and get together an outstanding committee of lay people because of the respect and trust the public had for him He inspired the British Columbia Cancer Foundation and raised large sums for it He was founder and chairman of the medical board of the British Columbia Medical Research Institute While president of the Canadian Medical Association he travelled from coast to coast lecturing and urging that more facilities for the rehabilitation of the handicapped be provided He had a real interest in England and the British Empire Last year he visited Australia and New Zealand as the president of the American College of Physicians, and on more than one occasion he visited Britain.

He was a first class internist and heart specialist, and his services were much in demand He was a very human man and his patients loved and trusted him for he gave them confidence, and seemed to understand the psychological side of their illnesses Before any major medical move took place here, the question always was "What does Fritz Strong think of this project ? " We will miss his kind heart, honest counsel jovial personality, and courageous leadership

Dr Strong leaves a widow and a daughter His only son was killed during the war while serving with the R C A F

KIYOSHI SHIGA

Professor Shiga will be remembered for his discovery of the dysentery bacillus that was named after him

He was born in 1870 the son of Shin Sato, a Samurai In 1886 he was adopted by Tasuku Shiga and the same year began his studies at the Imperial University in Tokyo After graduating he became an assistant at the Institute for Infectious Diseases in Tokyo, and it was in 1897, while he was working under Professor Kitasato, that he made his *observations on the dysentery* bacillus In 1901 he was sent by the Japanese government to Europe and he worked with Ehrlich in Frankfurt and later with Kossel at Heidelberg With Ehrlich he published experimental work on the chemotherapy of trypanosomiasis In 1909 he was sent on a scientific mission to India In 1912 he visited Europe again and for a year studied the chemotherapy of tuberculosis under Ehrlich He continued this work in Japan In 1920 he was appointed professor of bacteriology in the Imperial Keijo University in Korea

After the first world war, in 1924, Shiga attended some international conferences in Switzerland and then came to London to visit the National Institute for Medical Research, the Lister Institute, and the Wellcome Physiological Laboratories In 1929 he was appointed president of the Imperial University in Korea While he was in Korea he made a special study of leprosy and the culture of the lepra bacillus In 1931 he returned to Tokyo where he acted as consultant to the Kitasato Institute In 1936 he was appointed an official of the Imperial household

After the late war he retired to his native province, and he died peacefully at his villa at Sakamoto on Jan 25

RICHARD CHRISTOPHER CLARKE

O B E , T D , M B Brist , F R C P

Dr Richard Clarke's death on March 23, at the age of 71, breaks an association of nearly fifty years with the Bristol Royal Infirmary As student, resident, and honorary he served the institution with loyalty and devotion until he retired from the active staff in 1918 Despite his attachment to the traditions and history of the Bristol Royal Infirmary he had the vision to see the advantages to the Bristol Medical School which would follow from the amalgamation of the clinical schools at the Royal Infirmary and General Hospital, and he was one of a small group who planned and worked towards this end, which was achieved in 1940

He was educated at Clifton College and the University of Bristol, and he took his clinical course at the Middlesex Hospital in London After qualifying in 1910 he held a series of house-appointments at the Bristol Royal Infirmary

Even as a student he was an enthusiastic member of the Territorial Army, enlisting as a private in the Bristol Rifles, and in the 1914–18 war he served with the R A M C , for the greater part of the time with no 19 casualty-clearing station, and for his services he was appointed O B E Some twenty years later in his presidential address to the Bristol Medico Chirurgical Society he gave a vivid description of his struggles and achievements with the medical problems of the war in France

In 1913 he had been appointed assistant physician to the Bristol Royal Infirmary, and after he was demobilised he returned to Bristol to take up this appointment and resume his private practice in Bristol In 1921 he was appointed full physician In 1931 he was elected F R C P

During the years between the wars he served with the Territorial Force as medical officer to the 4th Gloucesters until in 1937 he was gazetted colonel to command the reconstituted Second Southern General Hospital In the late war he was in charge of a hospital with the Mediterranean Expeditionary Force

In 1925 he became a member of the Bristol Zoo Council, and three years later was elected chairman For the next thirty years he derived great pleasure from planning the development of the gardens and the care of the animals His disregard of convention served him well By discarding the traditional methods of coddling the inmates and by his early realisation of the importance of vitamins, nutrition, fresh air, and the avoidance of infection he had great success in maintaining the health and vigour of the animals, particularly the larger primates Perhaps two of his greatest achievements were the rearing of that fine gorilla Alfred and the birth of the first chimpanzee in this country

C B P writes

"As a physician Richard Clarke was an individualist, an original thinker, and something of an iconoclast as is shown by one of his earlier papers entitled *The Teething Myth* Though perhaps never recognised as a pædiatrician he was always keenly interested in infant welfare and the diseases of children and for many years ran an infant welfare clinic at the Royal Infirmary As soon as a department of child health was established in the university he endowed a prize in this subject His mercurial and vivacious personality endeared him to colleagues and students, and in fact to all with whom he came in contact We shall all miss his visits to the Royal Infirmary which he served so well"

Dr Clarke leaves a widow, a son, and two daughters

BERNARD ROWORTH TURNER

B A , M B Camb

Dr B R Turner, who died on March 20, went to Oundle as a general practitioner at the beginning of the century and settled there for the rest of his life, building up a fine practice in the school, the town, and the surrounding country, a farming area and a region of many great houses He was educated at the University of Cambridge and King's College Hospital, qualifying in 1802

C E N writes

Dr Turner owed his success to his personal qualities He was a good sound doctor, without any intellectual pretentions, and he never played at surgery, but he had two outstanding qualities he liked and understood people, and he knew when illness was serious When a case was within his scope, he dealt with it with confidence and efficiency when he thought it was beyond him, he had no hesitation in referring it to the expert, and he recommended the right expert He was a wise counsellor and a personal friend to all his patients That would not be a bad description of a good doctor, and he was a very good doctor , the kind which comes to mind on reference to "the family doctor," of which flower of the profession he was an outstanding example

He worked hard and conscientiously, but he found time to enjoy life Good food and drink, exercise, and the open air life he loved He played a good game of bridge (and of tennis in his younger days), he always had at least one dog in the car with him, and he was always ready to stop and talk His chief pleasure in life was people, and he had a wonderfully cheerful disposition, with a lasting almost boyish zest for life which was extremely attractive Some at least of it was the result of courage, for he had not always had the easiest path He was absolutely genuine, without pretentions, and with a deep underlying humility his attitude that the person he was talking to was more competent than himself to speak of this or that was no affectation It was no wonder he was so loved, and when people laughingly said that B R T stood for brotherly love, relief, and truth, they were being neither sarcastic nor pretentious

HILBRE HAMILTON WATTS

M B Lpool

Dr Watts, who died at his home in Hertford, on March 21 at the age of 41, was the elder twin son of Mr A T Watts, the founder of Kingsmead School Hoylake He was educated at Monkton Combe School and before starting medicine at Liverpool in 1930 he held a post with Imperial Chemical Industries for a short time At the university he made his mark on the rugger field and in the activities of the Student Christian Movement and Evangelical Union He qualified in 1942 and was house-surgeon to Prof Charles Wells at the Royal Southern Hospital, Liverpool, before being called up to the R A.M C While on active service in India he was stricken with poliomyelitis which left him severely crippled When he was able to start medical work again he found surgery too strenuous, and turned to pathology, but it did not satisfy his real zest for life Finally, after holding a registrarship in clinical medicine at the Royal Southern Hospital, he decided to enter general practice He was an assistant in Birmingham or a time and three years ago joined a partnership in Hereford

T L S writes

It will not be for his doctoring or his prowess on the rugger and cricket field that Hilbre Watts will be remembered, but rather for his deep abiding faith in God and His purpose Throughout his life he strove to influence others by his example, in particular through the Crusader groups which he led, first at Hoylake and then in Hereford and through the S C M and Evangelical Union at the university He overcame the physical handicaps which followed his illness with an inner reserve of courage and never complained, though for one who had been so active in outdoor sports his disability was particularly irksome At his funeral service in Hereford tribute was paid to his great contribution to the spiritual life of the city

Dr Watts leaves a widow and two young daughters

LAWRENCE WILLIAM CANN

M B Lond , D P H.

Dr Cann, pathologist to the Ashford County Hospital, Middlesex, died at the age of 56 on March 11 He qualified from Guy's Hospital in 1924 and was for a time assistant pathologist at Guy's, and while there he collaborated with De Navasquez in the preparation of a paper comparing the value of the Wassermann and Kahn reactions For some years he gave up medicine and only returned because of the need for pathologists during the war He joined the Emergency Pathological Service at Ipswich and was soon transferred to Ashford, where he played a vital part in building up the laboratory from small beginnings He gave particularly valuable service in visiting the smaller, outlying hospitals and seeing patients, in consultation with members of their staffs

W F H writes

Bacteriology was Lawrie Cann's main interest, and on any point raised, no matter how obscure, he would be sure to remember some relevant paper The details he could find at a moment's notice in his index This he kept up to date by constant revision—going through the old papers, rejecting selecting, and annotating He was an enthusiast in all matters relating to bacteriology A chance remark would set off a train of thought on which he would ponder for weeks, forming and if possible testing, theories

Cann was foremost a deeply religious man He thought much and read widely about the religions of mankind but his faith remained a simple one, free from creeds and dogmas and best expressed in his own words 'The Lord knows best', He had known for many years that he had severe mitral and aortic lesions the result of acute rheumatism, but he never let this knowledge interfere with what he conceived to be his duty And his duty to Cann was not only what he was paid for Even in the last year or two he insisted on undertaking far more than his share of the ever increasing burden of work

He sought no popularity but he became extremely popular with all sorts and conditions of men He has kept up correspondence with almost everyone who had worked in the laboratory He was a very modest man, and partly because of this, and partly because he thought of people as individuals and not in groups, he was content to exert his influence locally

He was always exasperated by rigid rules, particularly by the rigid salary scales of the ancillary workers in the laboratory "Here is a man" he would say, for example who has served this hospital for years He has a wife and family Surely we can pay him more Surely we can make him a senior' He would know quite well that there was no vacancy for a senior but that was a matter of small import to Cann I will not say that life in the laboratory with him was always blissfully peaceful, but then probably the last thing he sought was peace, not because he was a man of war or liked strife, but because he felt that we were not entitled to the joys of peace till every wrong was righted But he enjoyed life to the full He was a happy man with a keen sense of humour He enjoyed reading He appreciated music and the arts Pictures both ancient and modern had a great appeal He was very fond of flowers, particularly the less sophisticated varieties He loved children, but curiously, though always kind and gentle to them, he was not very fond of animals, he could be deeply moved by the beauty of an anemone but not by the grace of a pony in action He was a very sociable man Though he rarely gave formal invitations he always delighted to welcome the casual caller He dearly loved a party Above all he was a family man His chief delight was the time he spent with his wife and family, playing with the younger ones, talking to and reading with those older, and if we sometimes felt that he was too ready to involve them in his quixotic acts of self-immolation it was always with their consent, for every important action was discussed with them and agreed upon

Dr DESMOND FARIS

P M -B writes

The antimalarial measures which Faris organised and devised with such enthusiasm, together with Dr J W Scharff in the early 'thirties are generally recognised as an outstanding achievement in malariology and one which has played a great part in converting Singapore, and indeed Malaya in general, into the health resort that it has now become Malaya owes him another debt in the fine work that he did for its university He threw his heart into this task. He made a most admirable dean who, by his charm and accessibility held the various races and cliques together To visitors to Singapore he showed unbounded kindness and hospitality, and encouraged their interest in the everyday life of his university He did much for the dignity and efficiency of this growing institution, and his influence will remain as a binding tie among the racial rivalries of Singapore

Notes and News

NEW RATES FOR HOSPITAL STAFF

REGULATIONS[1] authorising an increase of 10% from April 1 in the salaries of all hospital doctors and dentists up to the grade of senior registrar were published last week An interim adjustment of salaries for these grades had been promised by the Prime Minister earlier last month The number of doctors and dentists affected in hospitals in England and Wales is about 8500

The new rates per annum for whole time appointments (with the old in parentheses) are

Senior registrar £1210 in first year (£1100), £1320 in second year (£1200), £1430 in third year (£1300), £1540 in fourth and any subsequent year (£1400)

Registrar £935 in first year (£850) £1061 10s in second and any subsequent year (£965)

Junior hospital medical officer commencing at £852 10s (£775) and rising by annual increments of £55 to £1182 10s (£1075)

Senior house officer £819 10s (£745)

House officer £467 10s for first post held (£425), £522 10s for second post held (£475), £577 10s for third and any subsequent post held (£525)

The total cost of the increases will be in the region of £900,000 a year

A statement issued last Monday by the British Medical Association criticised the Government because "no negotiation or even discussion took place before the increase of 10 per cent was decided on, although on February 20, Lord Salisbury, in the House of Lords, promised that the increase would be 'negotiated through the established Whitley [Council] machinery'—a promise repeated by the Minister of Health in the Commons on March 4" This, the statement continues, is "a flagrant breach of the pledge given to the hospital doctors in 1949 that no changes would be made in their terms and conditions of service without discussion in Whitley The manner of making this increase is naked dictation and nothing else"

EFFECTS OF RADIATION ON WOUND HEALING

SOVIET surgeons have lately been studying, by means of experiments on animals, some of the problems which may arise for the surgeon when irradiation damage is combined with mechanical trauma Prof N E Blenov[2] describes experiments in which guineapigs and rabbits were wounded after irradiation at doses of 400r and 600–800r respectively In the first experiment, 243 guineapigs were used, and it was found that wounds made half an hour after irradiation took, on an average, two days longer to heal In another experiment, 195 guineapigs were used and wounds were made three, six, twelve, and twenty four hours after irradiation There was primary healing in 30 out of 84 irradiated animals, and in 29 out of 51 controls (The "missing" animals appear to have died, there are no figures indicating the relative mortality of irradiated animals and controls) When suppuration followed, it became apparent several days later in the irradiated animals Similar experiments were done giving the animals streptomycin or penicillin—both locally and systemically These antibiotics assisted local healing but did not alter the overall mortality

Another series of experiments showed that irradiation delayed formation of callus in closed fractures in rabbits (112 irradiated, 24 controls) In open fractures too, callus formation was delayed, and there was a higher incidence of osteomyelitis and suppuration in the irradiated animals Blenov concludes that if a surgical operation must be done after exposure to irradiation, the sooner it is done the better, and surgical interference should be small and as gentle as possible He also concludes that wounds should be covered with sterile dressings (i e, not left open) and the limb immobilised Stitches should be left in place for at least three or four days longer than usual and fractures immobilised in plaster for at least two weeks longer Blood transfusion three days after irradiation helped healing and recovery from radiation sickness, and combined with the administration of streptomycin it lowered the mortality rate

Prof B M Chromov[3] investigated methods of cleansing wounds contaminated with radioactive material Wounds 2 cm long were made in the backs of rabbits and immediately contaminated with 20 microcuries of radioactive iodine isotop (^{131}I) Two hours later, the wounds were thoroughly excise and irrigated with various solutions (physiological saline, 3% soap, and 0 5% aqueous iodine) Thorough excision was foun to remove a third of the radioactive material, or half th material when combined with irrigation

UNIVERSITY APARTHEID

IT has been found that the parts of the Separate Universit Education Bill[1] dealing with the Natal non European medica school and the Fort Hare Native College would have t be submitted to a select committee, which would mea long delay before the Bill was finally passed The South African minister of education has accordingly withdrawn i and will introduce an amended Bill to establish university apartheid this session, leaving Fort Hare and the Natal medical school till later

The *Times* (April 2) reports that the students' representativ council of Stellenbosch University have issued a statement approving the principle of university apartheid but with a rider saying that this was not a direct endorsement of the government's Bill

NEW ORIENTATIONS IN RENAL DISEASE

MOST clinicians probably think of the kidney as primarily an organ of excretion The physiologist on the other hand pictures it as a homœostatic organ regulating the distribution of water and electrolytes in the body This conception, although not new, is exerting a growing influence on clinical medicine, as is evident from the latest issue of the *British Medical Bulletin*,[2] which is devoted to the physiology and pathology of the kidney The 16 articles, written by clinicians and edited by Prof Robert Platt, reveal how much has been added to our knowledge of the kidney in recent years

Flame photometry, chromatography, and the discovery of aldosterone have focused attention on the renal tubules, and have given a great impetus to the study of water and electrolytes R A McCance and E M Widdowson describe the homœostatic function of the kidney in the newborn O Wrong reviews the problems of dehydration and œdema with special reference to the kidney's rôle in the volume control of body fluids D A K Black and E W Emery, and M D Milne, R C Muehrcke, and B E Heard consider the complex relationships of the kidney in potassium metabolism, H Harris explains the significance of certain rare renal amino acidurias, M G McGeown and G M Bull discuss the pathogenesis of renal calculi and S W Stanbury in what is perhaps the outstanding essay of a distinguished collection throws new light on the way in which the failing kidney affects calcium metabolism and causes renal osteodystrophy

These metabolic studies are supported by new information about structure E M Darmady and F Stranack give an account of the technique of microdissection, which enables the morbid anatomy of an entire nephron to be examined in detail, while C R Macpherson and A G E Pearse show how the enzyme systems of the kidney can be studied histochemically In the living patient a new aspect of structure is being revealed by the radiologists, R S Murray and G C Tresidder describe what can now be learned from renal angiography while R E Steiner describes renal venography

Treatment and prognosis receive less attention than other aspects but C Wilson and D G Abrahams discuss the use of hypotensive agents in renal hypertension and J R Squire J D Blainey and J Hardwicke review the prognosis and treatment of the nephrotic syndrome which now has no less than fourteen known causes

The rôle of the kidney in hypertension remains obscure but M A Floyer and J M Ledingham describe some new advances in experimental hypertension The problem of the kidney in old age is represented only in so far as it affects the rat although pioneer studies in man have been reported in this country[3] It is none the less of great interest to learn that G C Kennedy has shown how senile changes in the rat's kidney can be accelerated both by overfeeding and by unilateral nephrectomy

This is an outstanding number of the *Bulletin*

A FILM ON EPILEPSY

People Apart is a 35 minute sound film about epilepsy It was made by Guy Brenton, who, with Lindsay Anderson wrote and directed the successful documentary *Thursday's Children* The medical supervision was by Dr Christopher Ounsted Most of it is a convincing account by patients of the illness seen from their own point of view, telling how it has affected their lives and work None are professional actors, but most speak fluently and attractively There is no sentimentality or pathos, but no attempt to gloss over their handicaps

Other parts of the film give some account of the nature of the disease Cerebral dysrhythmias are likened to the convulsive movements of a spraying hose which has been up and the depicted writhings of the hose strikingly counterpoi

the writhing of a patient in a major fit, which is shown in two or three sequences—a very severe fit which might be considered unsuitable for showing to a general audience Electro-encephalography, as shown, appears a rather frightening business

The main purpose of the film which was made for the British Epilepsy Association, 27, Nassau Street, London, W 1, seems to be to show that epileptics are ordinary people and generally employable It is unlikely to reach a wide public, but it is hoped that teacher s training colleges and welfare organisations will profit by it

JOURNAL ON MENTAL DEFICIENCY

THE first number of the *Journal of Mental Deficiency Research*, sponsored by the National Society for Mentally Handicapped Children, is to appear this spring Articles on all aspects of mental deficiency will be included, but there will be a medical bias and much of the space will be allotted to papers reporting original research.

The Journal will be administered by an advisory committee under the chairmanship of Prof L S Penrose F.R.S with Dr B W Richards as editor It will appear twice a year in the first instance The cost will be 7*s* 6*d* ($1 50) per issue Subscriptions should be forwarded to the Publishing Manager Mr A Highfield 10, Shendon Way Sevenoaks Kent. Inquiries and contributions should be addressed to Dr B W Richards St Lawrence s Hospital Caterham Surrey

---

University of London

Dr Katharine Lloyd-Williams has been elected dean of the faculty of medicine for the remainder of the period 1956–58, in succession to the late Prof W G Barnard

Dr Charles Harris has been reappointed deputy vice-chancellor for 1957–58

Royal College of Physicians of London

Prof G W Pickering will deliver the Croonian lectures on Tuesday and Thursday, May 14 and 16 at 5 P.M, at the college, Pall Mall East, S W 1 He will speak on the regulation of body temperature in health and disease

Sydney Body Lecture

Sir Hugh Linstead, M.P, will give this lecture at the General Hospital, Southend on-Sea, on Friday, April 12, at 8 30 P M He is to speak on human relations in and around the health service

Royal Society of Health

At a meeting of this society to be held at 90, Buckingham Palace Road, London, S W 1, on Wednesday, June 12, at 2 30 P M, Dr F G Spear will speak on the effects of radiation

Mental After Care Association

The annual meeting of this association will be held at Caxton Hall, London, S W 1, on Tuesday, April 16, at 3 P M, when Lord Pakenham will speak

Biochemical Society

A joint meeting of this society with the Societe Belge de Biochimie will be held in the department of biochemistry of the University of Oxford, on Friday and Saturday, April 12 and 13

Russian Tuberculosis Conference

A conference for all tuberculosis workers in the U S S R will be held in Moscow from June 9 to 15 1957, inclusive The agenda includes epidemiology of tuberculosis in the U S S R, vaccination and immunological problems anti bacterial therapy, and surgical treatment Visitors will be welcome, and further details may be had from Dr Lapina, director, Tuberculosis Division of the Ministry of Health Moscow

Medicinal Chemistry

A symposium on this subject is to be held by the Chemical Society, the Institute of Petroleum the Royal Institute of Chemistry, and the Society of Chemical Industry at the University of Manchester on Tuesday, April 16 at 9 30 A M The speakers will include Dr H C Carrington Dr A Spinks, Prof Henry McIlwain D SC Mr R B Rodnight Prof Franz Bergel, F R I C Dr A L Walpole and Dr Harold Jackson Further particulars may be had from Dr M G T Burrows, Murgatroyd s Salt & Chemical Company Ltd, Elworth, Sandbach Cheshire

Society for Cultural Relations with the U S S R

On Tuesday, April 9, at 8 P M, at 14, Kensington Square London, W 8, Dr Fedor Syrovatko, professor of obstetrics and gynæcology at the central medical postgraduate school in Moscow, will speak on Soviet work in the relief of pain in childbirth

Agricultural Research Council

Dr J W Howie, professor of bacteriology in the University of Glasgow, has been appointed a member of the council in place of Prof J S Young who has resigned

Group and Social Psychotherapy

A course on this subject will be held by the Institute of Social Psychiatry in collaboration with the Group Analytical Society from July 22 to 29 at Moor Park College, Farnham, Surrey Further information may be had from the institute, 9, Fellows Road London, N W 3

Advisory Committee on the Handicapped

The Minister of Health has announced that this committee to consider the health and welfare of the handicapped will meet under the chairmanship of Mr Edward Evans, M.P The 19 other members include the following doctors Dr T M Cuthbert, Sir Harry Platt, F.R C S, Prof A B Semple. and Dr J A L Vaughan Jones

Tribute to Sir Ernest Rock Carling

In celebration of Sir Ernest s 80th birthday on March 6, some of his friends held a dinner in his honour last Monday at the Royal College of Surgeons

Sir Stanford Cade, who presided, spoke of him as a man scrupulously punctilious in his life as a surgeon and a doctor, regarded with veneration, respect, gratitude, and affection With continuity of purpose in a varied career, he had always seemed to his juniors a little different from other surgeons, but forty years ago he had looked exactly as he did now Sir Adolphe Abrahams suspected that Sir Ernest, besides serving medically in the South African war and the two world wars, had been active in the Crimea and even the Indian Mutiny At Westminster Hospital, in whose new building he had been the dominating factor, he had gained eponymous immortality through the naming of a ward, but there was not a stone in the structure that did not bear the imprint of his personality Even if he had shown complete ineptitude in every other capacity, he would have earned lasting fame as a surgeon by his indefatigable generosity, his judgment and his skill His sympathy and skill had also been at the service of the profession through the Medical Protection Society Sir Clement Price Thomas said that his old chief had " meant an enormous amount in my life ' he remembered how when juniors made mistakes, it always turned out that Sir Ernest himself had made bigger ones

Sir Ernest quoted Kipling to the effect that no satisfaction on earth compares with that of approval of one s work by fellow workers, but he feared that a higher court would be more concerned with what he had *not* done—with the opportunities missed At least he could not be reproached he felt, for basking in the reflected glory of his former students and he went on to speak of the contributions of each of them and of what he owed to his colleagues at Westminster and to other members of the company—to Sir Henry Dale, who introduced him into the Medical Research Council, to Sir Wilson Jameson who sent him to the Home Office, to Sir John Charles his chief there to Sir George North for his association with the work of the General Register Office to Sir Landsborough Thomson, of the M R C, and to many others present, including some of those who have worked with him on radiological problems—W V Mayneord, B W Windeyer E E Pochin W P Grove Lord Amulree, J S Mitchell M Lederman, and D W Smithers The peak period of his life had, he thought, been during the war, when he had a share in the invaluable contribution made by the Medical Research Council, and the Atomic Energy Commission had given him his most interesting ten years

A presentation of inscribed cuff links was made to Sir Ernest, and Professor Mayneord handed him a book sent to their chairman emeritus by the International Commission on Radiological Protection—a body whose pre-eminence was largely due he said to Rock Carling s guidance The evening ended with a toast proposed by Sir Ernest, to Private Secretaries and Personal Assistants, whose work, he believes, all too seldom gets the recognition it deserves He coupled it with the name of his own secretary, Miss Barrie

Register of Nursing Research

The council of the Royal College of Nursing proposes to maintain a register of nursing research The librarian would be glad to receive information from individuals or organisations about completed work or work in progress The address of the college is Henrietta Street, London, W 1

Vocational Rehabilitation of the Disabled

The Government propose to accept a recommendation on the vocational rehabilitation of the disabled adopted at the 38th session of the International Labour Conference in 1955 (Cmd 111) The law and practice of the United Kingdom is generally in accordance with the provisions of the recommendation

International Society of *Bioclimatology* and *Biometeorology*

This society will hold its first scientific congress in Vienna from Sept 23 to 27 Further particulars may be had from Dr S W Tromp, Hofbrouckerlaan 54, Oegstgeest, Leyden, Holland

London College of Osteopathy

The Leverhulme Trust Fund is providing scholarships to enable qualified medical men and women to study osteopathy at this college The next course begins on Oct 8, and particulars may be had from the secretary of the college, 24, Dorset Square, London, N W 1

André Mayer Fellowships

The Food and Agriculture Organisation will offer six to eight of these fellowships in 1957 for research in agriculture, agricultural economics and statistics, fisheries, forestry, and nutrition Further information can be had from the secretariat of the F A O National Committee for the United Kingdom, c/o the Ministry of Agriculture, Fisheries and Food, Whitehall Place (East Block), London, S W 1

Portrait of Sir Geoffrey Keynes

The Osler Club held a ' cardiac surgery evening " on March 26 in honour of Sir Geoffrey Keynes's 70th birthday On behalf of the club Dr W S C Copeman, the president, presented him with his portrait by Mr Gilbert Spencer, A R A, who was present In a short address Sir Gordon Gordon Taylor extolled Sir Geoffrey's achievements in surgery, letters, art, bibliography, and the ballet Sir Russell Brock then spoke on the history of cardiac surgery and was followed by Sir Henry Souttar, Dr A H T Robb Smith, Sir Zachary Cope, and others The company included the presidents of the three Royal Colleges and of the Royal Society of Medicine

The Family Doctor in New Zealand

Sir Charles Hercus, dean of the Otago Medical School, in an oration to the biennial conference of the New Zealand branch of the British Medical Association in Wellington, said that the family doctor was becoming the pivot of the national health service People were looking to him as consultant in daily life as well as in the treatment of disease, and he was showing an increasing interest in preventive medicine In physiology, bacteriology, obstetrics, pædiatrics, and psychiatry, as well as in preventive medicine, we have endeavoured to give effect to this recommendation Unfortunately, in the young graduate's period of compulsory training in hospitals this aspect is almost entirely subordinate to clinical work His contact with the home and the team of workers concerned with the welfare of the family is broken For a considerable period of his postgraduate training there is a regrettable separation from the home environment where all the factors leading to ill health are to be found Some method has yet to be found to overcome this important gap in the doctor s postgraduate training '

ADDENDUM *Fractures of the Femoral Neck* —Dr D B Murray and Mr Stuart Young, whose article appeared in our issue of March 23 have asked us to say that they are particularly grateful to Mr William Sillar, who operated on many of the patients for offering these cases for review They would also like to acknowledge the detailed medical evaluation by Dr James Buchanan of Dr Laurence Scott's medical unit during 1954 and 1955

Changing Demands of Modern Work and Control

The Ergonomics Research Society is to hold a symposium on this subject at the University of Bristol from April 8 to 11 Further particulars may be had from Dr O G Edholm, department of human physiology, M R C Laboratories, Holly Hill, London, N W 3

Sir Philip Manson Bahr has been awarded the Emile Brumpt prize for 195[illegible] by the Faculty of Medicine and the Institute of Tropical Medicine of Paris

Brigadier G T L Archer, Q H S the Army's director of pathology is visiting the United States at the invitation of the U S Department of Defence to discuss Anglo American research in military preventive medicine

Diary of the Week

APRIL 7 TO 13

Sunday, 7th

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL University Street, W C 1

10 15 A M Dr W N Goldsmith, Dr P J Hare Common Affections of the Hand (Clinical demonstration for general practitioners)

Tuesday, 9th

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields W C 2

5 P M Mr H T Shaw Radical Surgery in Cancer of the *Extrinsic Larynx and Laryngopharynx* (Hunterian lecture)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W 1

8 P M *Psychiatry* Dr Denis Parr Homosexuality in Clinical Practice Dr Peter Scott Some Forensic Aspects of Homosexuality

Wednesday, 10th

UNIVERSITY OF LONDON

4 P M (Middlesex Hospital, W 1) Prof R M Janes (Toronto) Cancer of the Lung—Certain Consideration in its Diagnosis

ROYAL SOCIETY OF MEDICINE

4 30 P M *Physical Medicine* Dr Graham Weddell Dr G Gordon Dr R M Mason Referred Pain

5 P M *Epidemiology and Preventive Medicine* Dr A M McFarlan Dr R Irene Hutchinson, Dr R L O Williams Transmission of Infection

Thursday, 11th

ROYAL COLLEGE OF SURGEONS OF ENGLAND

5 P M Mr A A Jefferson Pituitary Chromophobe Adenomata and Rathke Pouch Cysts (Hunterian lecture)

DISEASE AND POPULATION*

A LESLIE BANKS

M A. Camb , M.D Lond , F R C P , D P H

OF LINCOLN'S INN, BARRISTER-AT-LAW,

PROFESSOR OF HUMAN ECOLOGY, UNIVERSITY OF CAMBRIDGE

IN medieval times the pattern of disease was such that a physician trained in an Eastern city could practise his art in Europe, subject only to the restrictions of language and certain modifications due to climate

The average expectation of life from birth in Europe did not exceed 19 years, and in the big cities was at times considerably less (Sand 1952) The biological balance was one of high birth-rates, high death-rates especially in infancy, diseased adults, and few old people

The underlying causes are sufficiently well known War, pestilence, famine, and the mass movements of people all predisposed to the great epidemics Severe malnutrition, bad housing, and lack of cleanliness encouraged the spread of disease, and parasitic infestations, both major and minor, were universal Above all were the effects of ignorance and superstition

The Changing Picture in the West

In Western Europe this pattern began to change about 250 years ago, and subsequent developments may be traced in four stages Firstly, the slow improvement in economic and social standards extending over the 17th, 18th, and 19th centuries resulted in increased wealth, better housing, improvement in the standard of nutrition, and a general awareness of the desirability of conserving life Secondly, from about the year 1848, came a deliberate and sustained attack on the faulty physical environment The quantity and quality of water supplies, the proper disposal of sewage, and improvement of housing and working conditions all received attention Next, towards the latter part of the 19th century, may be seen increasingly successful attempts to control the biological environment, beginning with the recognition of the nature of infection and the segregation of infectious cases in "isolation" hospitals Intensive study of the causes of the various infectious diseases led to effective measures for their prevention

The fourth stage—the improvement of the social environment—has reached its peak in the present century, with the organisation of health and welfare services on a national scale In this country, for example, the National Health Service, National Assistance, comprehensive education, housing and town planning, smoke control, the protection of water sources by river boards, and the safeguarding of the quality and quantity of food have all reached full development within recent years Above all, countries like our own can now rely on accurate statistics and stable government

Some of the results are quite extraordinary In England the year 1856 was a good one (Farr 1858) Potatoes were 26 lb for 1*s* in the wholesale market, and beef and mutton 5½*d* per lb The population of England and Wales was 19 million with a birth-rate of 34 5 and a death-rate of 20 5, but 20% of all deaths were due to acute fevers, and 25% of all deaths occurred in the first year of life In that year 94,000 infants died "Consumption," with 49,000 deaths, accounted for 12 7% of the total mortality Included in the principal causes of death were cholera, smallpox, typhus, and dysentery The average expectation of life from birth of the most favoured classes was only about 45 years, but, even so, the population was rapidly increasing, in spite of emigration It is worthy of note that 170,000 people emigrated in 1856 of whom 80,000 were Irish and 72,000 English and Welsh

Turn now to the year of my birth, in London in 1904 According to the report of the medical officer of health it was a hot dry summer, and "during these months there was consequently a great increase in infant deaths, due to epidemic diarrhœa" The infant-mortality rate was 155 per 1000 live births as compared with 24 9 today, and one seventh of all deaths were due to infectious disease Although the birth-rate was falling it was still high as compared with the present day, and so also was the death-rate The expectation of life from birth was now 40–45 years for all classes 90% of the London schoolboys examined in that year had dental caries and in 70% this was serious Ringworm was common and the report recognised want of cleanliness and lack of food as the principal evils of children (London County Council 1904)

Today the picture is again different The death-rate is low (11 7 per 1000), and so also is the birth-rate at 15 0 Children and adults are healthy, and the proportion of people aged 65 and over has risen to 11%, compared with 5% in the year 1901 The principal causes of death are those of middle life, with cardiovascular disease and cancer in the lead The death-rate from infection is insignificant, but there is increasing preoccupation with mental stress and illness, and with the neurotropic viruses

It seems clear that we can expect relatively little further improvement in our vital statistics, unless it becomes possible to prevent or cure cancer and circulatory diseases, and indeed we must expect, in our type of society, to face an increasing burden of the elderly infirm due to the numbers now surviving to later life

Disease in Underdeveloped Areas

We can be said to live in two worlds Approximately one-sixth of the population of the world are now healthy, and wealthy, although perhaps not particularly wise They are able to control their environment and, even more important, their rate of reproduction They have adequate food, shelter, and medical care

Before proceeding further, to discuss the so called underdeveloped areas of the world, it is necessary to stress the fallibility of the statistics Adequate statistics are available for about one-third of the world, rough estimates obtain for another third, while the statistics for the remainder are generally inadequate (United Nations 1952) It should be noted, also, that much of the data on which reliance is placed today was collected in the years immediately after the war It is possible, therefore, that this reflects the fluctuations following the second world war and does not truly mirror the conditions which would prevail in times of stability

The population of the world in 1954, according to the United Nations Statistical Office, was 2652 million (United Nations 1955) More than half (1451 million) lived in Asia, the remainder being distributed as follows

Europe	404	million
America	357	"
Africa	210	"
U S S R (not included in Europe or Asia)	214	"
Oceania	14	"

In parts of Asia and Africa the disease picture resembles that of medieval Europe, for the individual may suffer from five or six diseases The people are at risk from the killing diseases of temperate climates in addition to "tropical" diseases Severe malnutrition is common, and added to this are the harsh physical environment, poverty and ignorance, bad housing, and often the crumbling of the ancient social patterns Birth-rates are high, but so are death rates, and the natural picture of population has been one of slow increase with sharp cuts due to famines or epidemics

That was the picture in many areas until about ten years ago Indeed, the year 1947 may be considered, like the year of the Black Death, a turning point for the world, for it was then that the first effects of the mass attack on malaria became apparent

---

* Abridged from an address given to the Science Masters' Association on Jan 3, 1957

It is now possible to launch attacks on disease at national and international levels, and on several fronts at the same time Environmental sanitation is rapidly being improved, and especially the chlorination of water-supplies, so that cholera, dysentery, and enteric fever, are declining in importance Malaria, predominantly a disease of rural areas with 300 million cases a year in the world and 3 million deaths, is now being attacked through the mosquito at a cost of 15–50 cents per head In Ceylon in one year, 1947, the death rate was almost halved from this cause alone Yaws, which affects most land areas between the Tropics, can be cured by one injection of penicillin at a cost of 2 dollars per head Tuberculosis, the greatest killer of all, is now being assailed in many ways, including immunisation with B C G

Bilharzia, estimated in 1947 to affect 114 million people (Stoll 1947), is receiving increasing attention, and so also is hookworm, which by reason of its distribution from 36° north to 30° south of the Equator can affect half of the inhabitants of the world Trachoma, a serious cause of blindness in both arid and wet tropical and subtropical regions, is readily amenable to modern therapeutic and preventive measures

Malnutrition, as evidenced by beriberi, pellagra, scurvy, rickets, and nutritional anæmia, in addition to protein deficiencies under various titles such as that of kwashiorkor, is now being treated on a vast scale by the provision of vitamins and dried milk

The results are, at first sight, catastrophic, for, while death-rates are being cut by half, birth-rates remain high or are rising Examples of the high birth-rates prevailing in various parts of the world are the following

Venezuela	in 1955	47 1
Mexico	in 1954	46 4
Ceylon	in 1955	37 9
Chile	in 1955	35 0
India	in 1955	30 5

The corresponding rate for England and Wales is 15 per 1000 population

Many more people are now surviving to adult life and reproductive ages as a direct result of the control of the killing diseases But other factors are at work also The control of famine, the reduction of losses in small and local wars, improved transport and communications, rising economic standards, education, and good government, are all playing a part

Problems of Population

In Puerto Rico the expectation of life at birth has increased by over one year per annum since 1940 This is at least twice, and often three times, as high as the maximum national rates ever recorded in the populations of the West Even so, the Puerto Rico rates were doubled by Japan between the years 1947 and 1950 and trebled by Ceylon between the years 1946 and 1949 (Stolnitz 1955)

In India the infant mortality rate in 1910 was 260 per 1000 live births In 1951 it had fallen to 116 If this rate can be reduced to 35 within the next twenty years, as seems possible, it will have fallen from 260 to 35 in seventy years

In Brazil the crude death rate for 1940–50 was between 19 and 20 per 1000, whereas the birth rate for the same period was between 43 and 44 The rate of natural increase was 23 per 1000, and the expectation of life from birth has risen to 42 or 43 years

In the Sudan the pilot census of 1953 showed a crude death rate of 37 per 1000 and a birth-rate of 56 per 1000

Many parts of the world are, therefore, able to demonstrate changes in their vital statistics over a period of ten to fifteen years which took us seventy or more years to accomplish They can, in fact, go on and beat the Western figures for low death-rates because of their high proportion of young people

It is at first sight odd that Oceania should have the highest rate of increase at 2 5% per annum, but this is explained by immigration The United States of America and China come next with an increase of 2% per annum followed by Asia, Africa, and the U S S R with about 1 5% per annum Europe is well behind with 0 7% per annum

The average world population increase is about 1 5% per annum, and when it was thought that food production was only increasing at the rate of 1% per annum (0 04% in the Far East), the picture gave cause for immediate alarm The latest reports of food production, both as to quantity and stability of output, are more reassuring (Food and Agriculture Organisation 1956) Even so, after allowing for all statistical fallacies, 100,000 births a day are something to be reckoned with

The most recent World Health Organisation statistics show a tendency to stabilisation of birth and death rates in the period 1951–55, with a slight overall decrease (World Health Organisation 1956) The infant mortality rate is declining rapidly, and in 1955 Sweden set up a new record with 17 infant deaths per 1000 liveborn This is the lowest rate ever recorded in the world, and can be contrasted with 422 per 1000 in Maceio in Brazil in 1943 and 353 in Saigon in Vietnam in 1947 As the improvement of infant mortality rates turns on such matters as family income, feeding, housing, sanitation, the working conditions of women, and the control of mass diseases including malaria, it is a reliable indication of the measure of improvement of those conditions also

It should be remembered that only certain countries have an immediate population problem Egypt, for example, is heavily overpopulated, whereas Iraq and Persia are not In general, the problem appears in its most acute form in islands Quality, as well as quantity, is involved The fertility of the people of agricultural areas is particularly affected, and that of market gardeners and paddy and coconut workers in Ceylon is now 40% higher than that of the people of Ceylon as a whole That is, of course, primarily due to the control of malaria

When discussing the growth of population it is tempting to blame the doctors for upsetting the balance of Nature, and it is often forgotten that the people are themselves demanding the prevention of disease There are many other factors involved, besides the advance of medical science There is, for instance, the cultural pattern which demands large families , the duty, often reinforced by religion, to perpetuate the family , and the need of agricultural peoples, using primitive methods, for large families if they are to survive The removal of taboos on sexual intercourse, which in some parts of India covered as many as 120 days in a year (Chandrasekaran 1954), must also be taken into consideration It is possible also that the biologists may, as a result of their studies of population changes in animals, have something to contribute to our knowledge of the natural rhythm of growth of human populations

Population Control

The most obvious remedy is some form of birth control which would be widely acceptable The various methods include total abstention from sexual intercourse , partial abstention by the rhythm method, which requires an ability to count, the wish to cooperate, and some elementary knowledge of biology , mechanical methods which require a trained physician working in maternity and child welfare centres (which do not yet exist in many areas) and the "little pill," containing some substance which will interfere with the maturation of the sex cells or embryo If and when, the latter becomes available it will need to be tested manufactured on a commercial scale, and sold at prices which the people can afford—its use being acceptable to them

We must face the fact that there is no short cut, and that the present rapid growths of population will involve a period of turbulence and instability for the areas concerned for perhaps fifty years or more

Meanwhile the results of the medical advances have not all been bad Malaria control has resulted in large tracks of land being brought into cultivation, and the improved health of the workers has meant increased production, both of food and of industrial products The control of hookworm alone is said to increase the working efficiency of affected people by 25% or more, and similar results will attend freedom from other diseases The people most concerned are those living in the rural areas of the world and responsible for the production of food Improvements in transport and communications mean, in turn, the possibility of improved distribution of food

There is also the changing attitude towards women, with outlets other than marriage, in the fields of teaching, nursing, and industry Nor must it be forgotten that the means to combat ignorance and prejudice are becoming increasingly available, both by the extension of formal education and by the radio and television

Conclusion

The first and most urgent need is to obtain true and reliable statistics of population and of food production, so that we may have an accurate world picture There is also an urgent need for combined action to study the problems of areas where the pressures seem to be greatest The persons required for such investigations include geographers, biologists, agriculturists, economists, veterinarians, anthropologists, administrators, and medical men

Until we have full knowledge of the problems of population growth it will be as well to observe the ancient maxim, "festina lente," for the happiness of a people does not necessarily turn only on an increased expectation of life

in the 50 years of sexual activity, a healthy man produces a trillion sperms—to produce 4 children on the average 250,000,000,000 per child To gain an idea of what a trillion really means is like trying to encompass the magnitude of the national debt But let us try On Feb 10, 1938 the editor of the *Baltimore Sun*, concerned with the growing number of persons on the Federal payroll, then 1,000 000 published on the editorial page what looks like a blank, but actually contains a newspaper half tone of 1,000 000 dots —1,000 rows of 1 000 dots each A lot of dots! However, to represent the number of sperms a man can produce in a lifetime would require a million editorial pages like this The paper necessary to produce 1,000,000 such pages would require 5 acres of forest trees Let me however inject at this point that this selfsame man also has a quadrillion of brain cells which are always available for the exercise of reason and self control!—Dr CARL G HARTMAN, *Trans Amer gynec Soc* 1956, 79 xcviii

REDUCED EFFECT OF HETEROLOGOUS INTRINSIC FACTOR

AFTER PROLONGED ORAL TREATMENT IN PERNICIOUS ANÆMIA

MICHAEL SCHWARTZ
M.D Copenhagen
PHYSICIAN AND LECTURER

PER LOUS
M D Copenhagen
DIRECTOR, DEPARTMENT OF CLINICAL BIOCHEMISTRY

EINAR MEULENGRACHT
M D Copenhagen
PROFESSOR OF CLINICAL MEDICINE, DIRECTOR, MEDICAL DEPARTMENT B

BISPEBJERG HOSPITAL, COPENHAGEN

ORAL administration of vitamin B_{12} plus intrinsic factor represents a rational treatment of pernicious anæmia, and this combination has come into wide use in the past three or four years With such treatment, however, in some cases a good initial response has been followed by a decrease in hæmoglobin level and red-cell count (Mollin and Ross 1954, Meulengracht 1955, Norregaard 1955, Lowenstein et al 1956)

In the past two years we have observed this phenomenon several times Occasionally, the blood status may be improved by increasing the dosage, but usually the oral treatment has to be supplemented by injections Vitamin B_{12} intramuscularly or liver preparations with vitamin B_{12} have always resulted in hæmatological remission Fig 1 illustrates this form of response in one of our patients

Using ^{60}Co-labelled vitamin B_{12} we have investigated the absorption of vitamin B_{12} and the effect of intrinsic factor in different groups of patients with pernicious anæmia As a result of this investigation, we have demonstrated the reason why oral treatment fails in some patients

Material and Method

Our series of patients may be divided into three groups A, untreated pernicious anæmia, B, injection-treated, with vitamin B_{12} or liver preparation, C, orally treated for six months to four years with preparations containing hog pyloric mucosa plus vitamin B_{12}

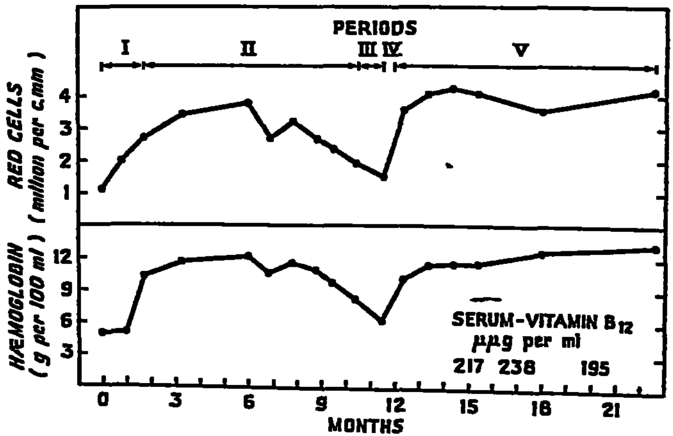

Fig 1—Blood findings and treatment in case of pernicious anæmia.

Period I 'Cycoplex' 6 capsules daily Period II. cycoplex 2 capsules daily Period III cycoplex 6 capsules daily Period IV liver extract intramuscularly for six days (a total amount of 540 μg vitamin B_{12}) Period V 'Exopylorin' 5 g daily (1 capsule of cycoplex contains vitamin B_{12} 5 μg plus dried hog pyloric mucosa 50 mg 5 g exopylorin contains 3 5 g dried total hog pyloric gastric wall plus 1 5 g dried liver residue from manufacture of liver-extracts)

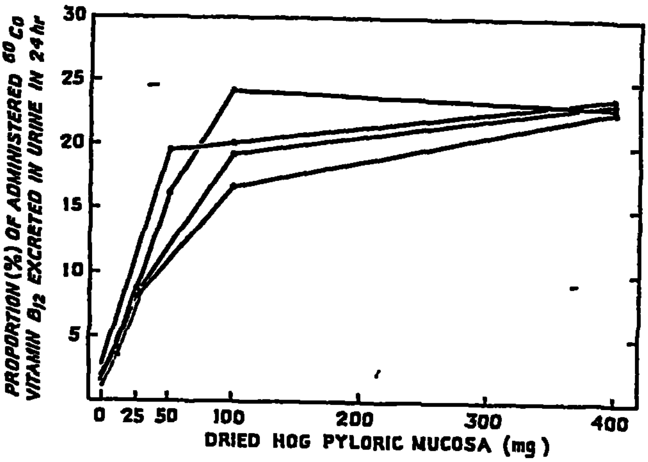

Fig 2—Urinary excretion in Schilling test performed with different amounts of hog pyloric mucosa in 4 patients with untreated pernicious anæmia

The method used in the investigation was the Schilling (urinary excretion) test 0 5 µg labelled vitamin B_{12} (0 1 µC) is given by mouth, and two hours later 1 mg unlabelled B_{12} is injected intramuscularly, urine is collected for twenty four hours All patients had a normal kidney function as measured by endogenous creatinine clearance In healthy subjects we had previously found by this technique a urinary excretion of 10–38% of the dose In patients with pernicious anæmia the excretion ranged from 0 to 8%

Results

Fig 2 shows the results in untreated patients (group A) A dosage response curve was plotted for the preparation dried hog pyloric mucosa An increased dose of intrinsic factor was found to give a larger urinary excretion, indicating increased intestinal absorption This "stoichiometric" relationship applies only, however, up to a certain limit If the amount of intrinsic factor is increased beyond this limit, there will be only a slight increase in the absorption of vitamin B_{12} These results confirm previous findings

In the same way, we studied 2 patients who had been on injection treatment for more than three years (group B) Fig 3 indicates that these patients show the same absorption as untreated patients

On the other hand, the study of 9 patients who had been on oral treatment (group C) for six months to four years gave quite a different result Fig 4 shows that of these 9 patients 7 exhibited an absorption of vitamin B_{12} which, with the same dose of intrinsic factor, was decidedly inferior to that found in groups A and B Only 2 patients of group C showed the same absorption as groups A and B Of the 7 patients with poor absorption only 3 had been showing a falling hæmatological status for some months The duration of the disease did not appear to be of decisive significance

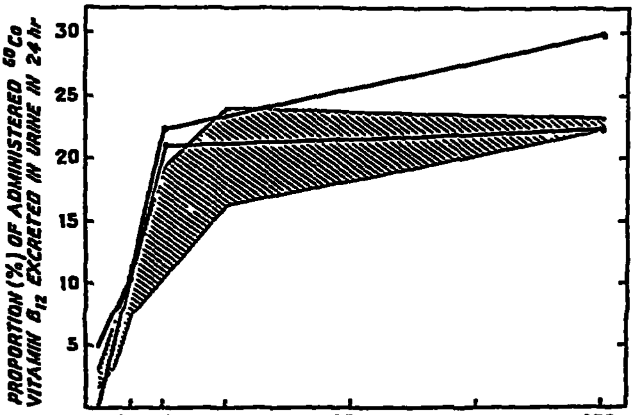

Fig 3—Urinary excretion in Schilling test performed with different amounts of hog pyloric mucosa in 2 patients with pernicious anæmia treated by injection for three years (Hatched area represents values for 4 untreated patients)

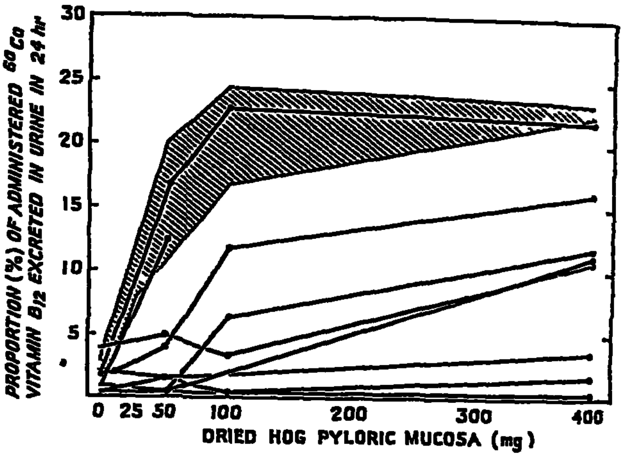

Fig 4—Urinary excretion in Schilling test performed with different amounts of hog pyloric mucosa in 9 patients with pernicious anæmia, orally treated for a half to four years (Hatched area represents values for 4 untreated patients)

In addition to these 9 patients, we studied 6, also on oral treatment They are not included in fig 4, as they had only a few doses of intrinsic factor, but the results were exactly the same

URINARY EXCRETION IN SCHILLING TEST PERFORMED WITHOUT INTRINSIC FACTOR AND WITH TWO DIFFERENT SOURCES OF INTRINSIC FACTOR FIGURES ARE PERCENTAGES OF ADMINISTERED ^{60}Co VITAMIN B_{12} EXCRETED IN URINE IN TWENTY FOUR HOURS

Patients	Intrinsic factor		
	None	400 mg dried hog pyloric mucosa	100 ml human gastric juice
Orally treated pernicious anæmia	1 7 0 0 3 7 0 6 1 8	0 1 8 3 7 11 2 11 6 16 4	21 0 23 4 15 5 30 1 22 0 18 8
Untreated pernicious anæmia	1 7 0 7 2 7	22 6 22 2 23 2	20 9 24 3 20 7

The intrinsic factor preparation used in these experiments was not highly purified We therefore repeated the experiments, using a highly purified preparation of intrinsic factor also made of hog pyloric mucosa In untreated and injection treated patients 2 mg of this preparation gave maximal absorption of vitamin B_{12} whereas in orally treated patients even 4 mg gave very poor absorption

As far as we know, this finding has not previously been reported It raises numerous new problems of theoretical and practical interest

All commercial stomach preparations are made of hog stomachs, so the intrinsic factor administered in treatment is of heterologous origin Our orally treated patients with poor absorption were therefore given human intrinsic factor in the form *of 100 ml human* gastric juice administered with the labelled vitamin B_{12} The results are given in the accompanying table, which shows that after administration of human intrinsic factor there is no demonstrable difference between orally treated and untreated patients

2 patients of group C were also given 100 ml human gastric juice, but neutralised to pH 7 This resulted in exactly the same good absorption as administration of acid gastric juice Conversely, we were unable to increase the absorption of B_{12} in group C by adding 100 ml 0 1 *N* HCl plus pepsin to the hog pyloric mucosa preparation

At present we cannot explain these phenomena Possibly the intramural "intestinal acceptor" postulated by Glass et al (1954) is affected by long term treatment with heterologous intrinsic factor

Summary

In patients with untreated pernicious anæmia the absorption of vitamin B_{12} can be considerably increased by quite small amounts of hog pyloric preparations

After treatment for some time with preparations of vitamin B_{12} plus pyloric mucosa, this absorption is more or less distinctly "blocked" in some cases The cause of the "block" is not yet known, but it is not present when homologous intrinsic factor is administered

This "block" is presumably the cause of the failure in some cases of oral treatment with preparations of vitamin B_{12} plus intrinsic factor.

We wish to thank Dr Lester Smith of the research division, Glaxo Laboratories, for supplying part of the labelled vitamin B_{12}, and Medicinalco Ltd and Gea Ltd, both of Copenhagen, for liberal supplies of the intrinsic-factor preparations This study was supported in part by the Statens Videnskabsfond, University of Copenhagen

CARBUTAMIDE (N (*p* aminophenylsulphonyl) N^1 [*n*-butyl] urea) and tolbutamide (N (*p*-tolylsulphonyl) N^1 [*n* butyl] urea) in a dosage of 20–80 mg per kg of body-weight daily (Bertram et al 1955, Franke and Fuchs 1955, *Deutsche Medizinische Wochenschrift* 1956) reduces the blood sugar level in healthy people and some diabetics

Several points in carbohydrate metabolism have been suggested for the action of these sulphonylureas they may reduce the absorption of carbohydrate from the gut (Friedlich et al 1956), stimulate the secretion of insulin from the pancreas (Kracht and Rausch Stroomann 1956), enhance the action of insulin in the tissues by inhibition of the enzymes which destroy insulin (Mirsky et al 1956), depress the secretion of the hyperglycæmic factor, glucagon, from the α cells of the pancreatic islets, or inhibit hepatic glucose-6-phosphatase with the result that the breakdown of glycogen to glucose is reduced (Hawkins et al 1956)

Most of these hypotheses are based on experiments with large doses in animals We undertook the following studies to determine whether evidence for any of them could be obtained in man

Investigation

To investigate different aspects of carbohydrate metabolism the following tests were made before, and repeated during, treatment with the sulphonylureas

(1) Carbohydrate digestion and absorption were investigated by using a standard breakfast test (Duncan 1947) and by oral and intravenous glucose tolerance tests

(2) Sensitivity to the action of insulin was investigated by combining an injection of soluble insulin with the above mentioned tests

(3) The arteriovenous difference in blood-sugar levels was measured during the glucose tests

(4) Because of its bearing on the arteriovenous difference the peripheral blood-flow was measured in the forearm

(5) Possible alteration of intermediary carbohydrate metabolism was investigated by measuring the level of α keto acids in the blood during the tests

(6) Glycogenolysis in fasting patients was investigated by injecting a test dose of glucagon intravenously

Clinical Material

29 patients, with fasting blood-sugar levels above 100 mg per 100 ml, were selected from the Guy's Hospital diabetic clinic because it seemed likely that they would respond to the hypoglycæmic agents, or because diet and insulin had not controlled their diabetes

The group consisted of 17 females and 12 males aged 16–82 (mean 61) The average duration of diabetes was 6¹/₂ years 11 patients were obese and 7 thin 20 of them had complications of diabetic origin 10 had diabetic cataracts, 7 diabetic retinitis, 10 vascular disease, 3 albuminuria and 11 neuropathy

Each patient was studied in hospital for at least three weeks The diet which had been prescribed at the clinic was continued in hospital Its preparation was supervised by a dietitian Any insulin required was given as the soluble preparation two or three times a day

Laboratory Methods

Routine

The 24-hour urinary excretion of glucose was measured by the quantitative Benedict (1911) method, and colorimetric estimations of glycosuria and acetonuria were made at 4 hour intervals throughout the day. Samples of capillary blood were taken each day at 2 30 P M for estimation of the blood sugar level by the Schaffer-Hartmann method as described by King and Wootton (1956) The patients were weighed and had their blood-pressure recorded every day, and, when carbutamide was given, its concentration in the blood was estimated daily Blood-counts, including a platelet-count, were done before and during treatment

Experimental

After at least 5 days' acclimatisation to the hospital, control tests were made in different patients In each test the patient fasted overnight (16 hours) and in the morning remained quietly in bed No therapeutic insulin was given on the morning of the tests Samples of fasting capillary blood was taken for estimating blood-sugar levels, and venous samples were drawn without stasis from an antecubital vein for measuring blood-sugar and blood α-keto acid levels by the method of Friedemann and Haugen (1943) Carbohydrate alone or with insulin was given in one of three ways 50 g

TABLE I—EFFECT OF SULPHONYLUREAS ON FASTING BLOOD-SUGAR LEVEL

Case no	Sex	Age (yr)	Age at diagnosis (yr)	Fasting blood sugar level

of glucose dissolved in water was given by mouth, or 20 g. of glucose was given as 50% solution intravenously, or a carbohydrate meal was eaten. In the insulin tests soluble insulin (7 units) was injected intravenously as the glucose was administered or immediately after the test breakfast. Capillary blood was taken at 15-minute intervals for the first hour and at 90 minutes. A second venous sample was drawn for estimating blood-sugar and blood-α-keto-acid levels at 1 hour. In the glucagon tests 1.0 mg. of glucagon was injected intravenously, and capillary blood for estimating blood-sugar levels was obtained at 15 minute intervals for an hour and at 90 minutes after the glucagon had been given. Initial doses of 3.0–4.0 g. of sulphonylurea were followed by 2.0–3.0 g. daily, until the levels of sugar in blood and urine fell. The dose was then reduced as necessary to prevent hypoglycæmia. If the level of glucose in blood and urine had not fallen after 3 days, the dosage was raised to 3.0–4.5 g. daily to achieve the required effect. The tests were then repeated in the same patients at least 7 days after the start of sulphonylurea treatment.

In certain special investigations described the forearm blood-flow was measured in conjunction with capillary blood sugar estimations. The blood-flow was determined with a venous occlusion plethysmograph (Grant 1938) operated at 34°C. Three blood-flow determinations were made before each capillary sample was withdrawn. In some patients forearm blood-flow was measured in the early afternoon before and during sulphonylurea treatment.

Results

Clinical Findings

It is not our purpose to describe the clinical aspects of this study. Our findings agree with those of the symposia published during 1956 in the *Deutsche Medizinische Wochenschrift* (1956), *Canadian Medical Association Journal* (1956), *British Medical Journal* (1956), and *Metabolism* (1956).

Blood sugar

A hundred carbohydrate tolerance tests of various types were made. The most obvious change in 22 of 29 patients during sulphonylurea therapy was *a fall in the fasting blood sugar level*. In table I we have arranged our patients in order of % fall in fasting blood sugar levels. We have arbitrarily classified those with a *fall* of more than 15% as having reacted (cases 1–22). This classification is not intended to imply that the diabetes of the patients who react could be controlled satisfactorily by sulphonylurea compounds either alone or in conjunction with insulin. We now know that in only 12 of these patients was sulphonylurea of practical value in their prolonged management.

Table II summarises the mean capillary blood sugar levels in the various tests carried out in the patients who responded. The lower level of fasting blood sugar during treatment is not associated with any marked change in the mean rise, or fall, of blood sugar during the tests. The sulphonylureas caused no significant difference in the reduction by insulin of the hyperglycæmia following the oral administration of glucose or the standard breakfast, but *in the intravenous glucose insulin test* the changes in blood sugar level at 60 and 90 minutes, taken together, were significantly different during treatment ($p = 0.05$).

The arteriovenous differences of blood sugar levels, in both the fasting state and at 1 hour during the various tests, were so variable that it would only be misleading to present them as indicating the peripheral uptake of glucose. This question is discussed later.

TABLE II—BLOOD-SUGAR AND BLOOD-KETO-ACID LEVELS IN VARIOUS TESTS BEFORE AND DURING SULPHONYLUREA TREATMENT

Test		Case nos	Blood sugar level (mg. per 100 ml.)					Mean rise in blood α-keto acid level at 60 min. (mg. per 100 g.)
			Mean fasting	Mean change at				
				15 min	30 min	60 min	90 min	
1 *Oral glucose*	Before During	3, 7, 11, 12, 17, 18	211 136	+61 +58	+92 +78	+150 +135	+130 +126	0.18 0.01
2 *Oral glucose and insulin*	Before During	1, 3, 7, 11, 12, 13, 17, 18, 21	211 128	+1 +2	+19 +36	+80 +66	+83 +78	0.70 0.63
3 *Insulin response from 1 and 2*	Before During	3, 7, 11, 12, 17, 18		62 48	13 39	86 85	57 75	
4 *Intravenous glucose*	Before During	4, 5, 6, 14, 15	226 100	+116 +121	+99 +96	−56 −57	−13 −35	0.03 0.13
5 *Intravenous glucose and insulin*	Before During	4, 6, 11, 15, 22	176 105	−80 −92	−53 −47	−30 −11	1 −21	0.72 0.13
6 *Breakfast*	Before During	2, 8, 10, 16, 19, 20	177 94		−86 −73	−125 115	−133 −118	
7 *Breakfast and insulin*	Before During	2, 8, 10, 16, 19, 20	177 109		−69 −58	−80 +86	−52 −81	

Blood-α-keto acids

The mean fasting level of blood-α-keto acids before treatment was within normal limits (0 96 mg per 100 g) There was a small but statistically significant (p = 0 02) fall to 0 86 mg per 100 g during sulphonylurea therapy The changes in the α-keto acid levels at 1 hour in the various glucose-tolerance tests are shown in table II All are within normal limits, and none of the changes observed after therapy is statistically significant It is concluded that small changes in the fasting level of blood α-keto-acid may take place during sulphonylurea treatment, but further studies are required to define which α-keto-acids are affected

Peripheral Blood-flow

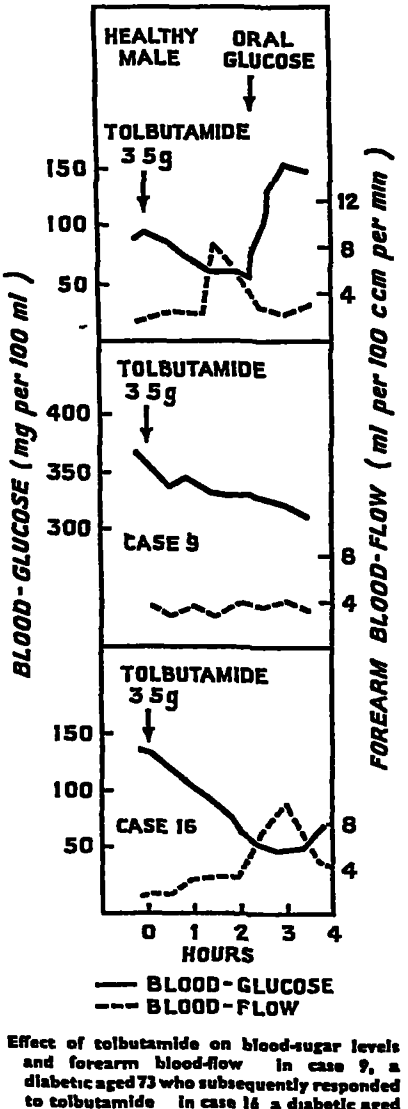
The following studies stemmed from the appreciation that changes in peripheral blood-flow must be taken into account if arteriovenous differences are to be regarded as an indication of the rate of uptake of glucose by the tissues

The forearm blood-flow was measured in 7 diabetics before and after more than 7 days' treatment with tolbutamide There was an increase in resting flow from a mean of 2 06 to 2 87 ml per 100 ml of forearm a minute For the group of patients this evidence of vasodilatation is just statistically significant (p = 0 05) This finding obviously complicates the interpretation of any arteriovenous differences in blood-sugar levels

The possibility *that tolbutamide* has a vasodilator effect was investigated The effect of 3 5 g of tolbutamide on the blood-sugar level and forearm blood-flow during the first 4 hours after its ingestion was observed in 3 fasting persons a diabetic aged 73 (case 9) who did not develop hypoglycæmia during this time, a diabetic aged 55 (case 16) who did, and a healthy male, who also developed hypoglycæmia The results of these tests are shown in the accompanying figure

In the elderly diabetic the blood sugar level fell only from 370 to 315 mg per 100 ml, and there was no significant change in blood flow

In the other diabetic the blood-sugar level fell from 145 to 55 mg per 100 ml, when the forearm blood-flow abruptly increased three fold and then returned to normal as the blood sugar level rose again



Effect of tolbutamide on blood-sugar levels and forearm blood-flow in case 9, a diabetic aged 73 who subsequently responded to tolbutamide in case 16 a diabetic aged 55 who responded more rapidly and in a healthy male

TABLE III—MEAN BLOOD SUGAR LEVELS IN GLUCAGON TEST BEFORE AND DURING SULPHONYLUREA TREATMENT

—	Mean blood sugar level (mg per 100 ml)					
	Fasting	Change at				
		15 min	30 min.	45 min	60 min	90 min
Before	216	—43	+62	+62	+52	+31
During	105	+44	+59	+69	+39	+23

In the healthy male the blood sugar level fell from 90 to 56 mg per 100 ml There was an abrupt fourfold increase of forearm blood-flow at the low blood sugar levels 50 mg of glucose was given, and the blood-sugar level promptly rose to 140 mg per 100 ml with a concomitant decrease in blood flow The blood sugar level subsequently fell (not shown in the figure), indicating that the tolbutamide was still active

We, like others, have observed a similar vasodilatation not only during hypoglycæmia caused by insulin but also during the infusion of adrenaline However, we are careful to attribute the vasodilatation only to the general response to hypoglycæmia, since Ginsburg and Paton (1956) have reported it in hypoglycæmic adrenalectomised patients Though tolbutamide does not immediately cause vasodilatation, the possibility that its prolonged administration is associated with vasodilatation requires further investigation

Glucagon Tests

The fasting blood sugar level is probably maintained by the continuous breakdown of hepatic glycogen to glucose—a breakdown in which the enzyme glucose 6-phosphatase is concerned The results of some experiments on animals suggest that the sulphonylureas inhibit glucose 6 phosphatase, and the results of the tolerance tests do not contradict this hypothesis We tested the facility with which glycogen is broken down to glucose, before and after sulphonylurea therapy, by observing the hyperglycæmic effect of 1 mg of glucagon on 9 patients who responded to sulphonylureas by a fall of fasting blood-sugar level The results are given in table III, which shows that, after treatment, there is a slight reduction of the hyperglycæmic effect of glucagon towards the end of the test, but none of the changes is significant We therefore conclude that further studies are unlikely to show any significant effect of sulphonylurea on the hyperglycæmic response to 1 mg of glucagon

Discussion

The results of our glucose-tolerance tests are essentially similar to those reported by other workers (Duncan et al 1956, Fajans et al 1956, Purnell et al 1956, Renold et al 1956)

The breakfast and the glucose tolerance tests show that the sulphonylureas neither retard the digestion of carbohydrates nor impede the absorption of glucose Furthermore, such actions would not explain the fall of blood sugar level when these compounds are given to fasting people

Phosphorylation and dephosphorylation of glucose take place in the liver and in the cells lining the intestines The fact that the absorption of glucose is unaltered shows that the sulphonylureas do not interfere with the action of glucose 6 phosphatase in the gut wall Unaltered glycogenolysis after the intravenous injection of glucagon indicates that the glucose 6 phosphatase of the liver is not blocked either

We have little evidence that the sulphonylureas affect the action of injected insulin Response to insulin can be judged by the alteration of the oral glucose curve when insulin is given The absence of any significant change in this during sulphonylurea treatment argues against enhanced insulin action (table II) On the other hand, during sulphonylurea treatment the action was achieved at a lower level of blood-sugar, which fact might mean that the insulin was more effective We find it difficult to accept this proposition We would expect an enhanced insulin action to alter the form of the glucose insulin curves In fact the sulphonylureas regularly produce lower but otherwise unchanged oral glucose insulin curves Therefore we are not persuaded that they render insulin more effective by suppression of insulinase or by interfering with insulin binding in the plasma

The only significant change in the various tolerance tests during sulphonylurea therapy took place at 60 and 90 minutes in the intravenous glucose insulin tests, when the blood sugar level was falling below the fasting level The records of Cox et al (1956) show a similar effect

This inability to regulate a falling blood-sugar level during treatment could be due to increased secretion of insulin or to a failure of the adrenal or pancreatic hyperglycæmic mechanisms Loubatières (1946) first suggested that the sulphonylureas act by stimulating the secretion of insulin Since we know that our patients were sensitive to insulin we cannot reconcile his hypothesis with the unaltered tolerance of oral and intravenous glucose during treatment Furthermore, the changes in fasting level of blood α-keto-acids was in the reverse direction to that observed after the injection of insulin The persistence of the diabetic form of glucose tolerance during treatment is evidence that the sulphonylureas do not truly correct the diabetic state, which fact is pertinent to the question of their ultimate place in the treatment of diabetes mellitus

The sulphonylureas do not act by blocking either adrenal or pituitary hormones There is evidence that they lower the blood-sugar level in patients with pituitary insufficiency and in patients with Addison's disease (Goetz et al 1956) and in hypophysectomised and in adrenalectomised animals (Houssay and Penhos 1956) Moorhouse and Kark (1956) have shown that the hyperglycæmic response to 1 mg of adrenaline is unaltered by tolbutamide, and we have shown that the adrenaline-like reaction to hypoglycæmia caused by tolbutamide occurs as readily as when the hypoglycæmia is caused by insulin

There remains for discussion the possibility that the sulphonylureas affect the production or action of glucagon Our patients showed no change in the hyperglycæmia after the administration of 1 mg of glucagon, indicating that there was no gross inhibition of the response to this large dose Similar results showing that the action of such doses of glucagon is not affected are mentioned by other workers (Moorhouse and Kark 1956, Volk et al 1956) We cannot draw any conclusion about the production of glucagon, there being no reliable method of estimating glucagon levels in man We had hoped to derive some information from our measurements of the arteriovenous differences in blood sugar levels because Elrick (1956) had shown that the administration of glucagon increased that difference We noted a statistically insignificant decrease of the arteriovenous difference at 1 hour in most tolerance tests after the administration of sulphonylurea Unfortunately no definite conclusions about the production of glucagon can be drawn from these results because the arteriovenous difference must depend on the peripheral blood flow, and we cannot be sure that this was the same when each test was repeated Clearly, if the action of the sulphonylureas on glucagon is to be settled by measuring the uptake of glucose more elaborate techniques than have been used hitherto will be required

Thus we have no evidence that the hypoglycæmic action of the sulphonylureas is mediated by any of the mechanisms so far suggested by the results of experiments on animals Although some of our findings might be construed as arguments that the sulphonylureas enhance the action of insulin, our present view is that the predominant changes occur in the mechanisms controlling the fasting blood sugar level, and that all other factors are essentially unaffected

Summary

The effect of 7 days' treatment with sulphonylurea (with and without insulin) on various carbohydrate tolerance tests, arteriovenous differences in blood sugar levels, blood-α-keto acid levels, peripheral blood flow, and the hyperglycæmic response to injected glucagon were studied in 29 diabetics

In 22 patients the fasting blood sugar fell more than 15% The only significant ($p = 0\ 05$) change after treatment in the various tests was in the intravenous glucose tolerance test, where the blood sugar level fell below the fasting level at 60 and 90 minutes

There was a significant ($p = 0\ 05$) increase in the forearm blood flow during treatment Such changes in peripheral blood flow complicate the interpretation of arteriovenous differences in blood-sugar levels There was a small but significant ($p = 0\ 02$) fall in the fasting level of α keto acids

The hyperglycæmic response to 1 mg of glucagon injected intravenously was not significantly changed after treatment

The hypoglycæmic action of the sulphonylureas in diabetics does not appear to be mediated by any of the mechanisms so far suggested by the results of experiments on animals

We wish to acknowledge the technical assistance of Caroline Hole, Janet Thomas and David Nancarrow, the facilities provided by Dr W N Mann, director of the department of medicine, and by Prof R H S Thompson and his colleagues of the department of chemical pathology, Guy's Hospital Medical School, the cooperation of Sister J Bennett and the nurses of William Gull Ward, Guy's Hospital, and the provision of carbutamide, glucagon, and insulin (free from hyperglycæmic factors) by Dr F B Peck, of Eli Lilly and Company, and of tolbutamide by Dr R H W Britton, of Horlicks Ltd

INFECTIOUS DISEASES DEPARTMENT, WHITLEY HOSPITAL, COVENTRY

REPORTS have lately appeared of several similar outbreaks of acute paretic illness, of which four occurred in Britain, and the term "benign myalgic encephalomyelitis" has been suggested for this condition (*Lancet* 1956) In one of these outbreaks infectious diseases staff in a Coventry hospital were affected when nursing similar cases admitted as poliomyelitis from the surrounding area in the summer of 1953 (Macrae and Galpine 1954), in three of the staff an electromyogram was taken and an abnormal discrete pattern found Ramsay and O'Sullivan (1956) describe cases seen in an area in north-west London and give details of abnormal electromyograms

We report here 7 further cases which arose sporadically in the Coventry area in 1956 They gave clinical and electromyographic findings which recalled those of the paretic cases seen in 1953

Case 1, female, married, aged 22, admitted July 10 as ? paralytic poliomyelitis, discharged July 26

Case 2, female, married, aged 20, admitted July 13 as ? paralytic poliomyelitis, discharged Aug 14

Case 3, male, unmarried, aged 17, admitted July 20 as ? paralytic poliomyelitis, discharged Aug 24

Case 4, female, married, aged 44, admitted Aug 29 as pyrexia of unknown origin, discharged Sept 14

Case 5, male, married, aged 33, admitted Sept 25 as ? paralytic poliomyelitis, discharged Oct 18

Case 6, male, married, aged 28, admitted Sept 27 as ? paralytic poliomyelitis, discharged Oct 8

Case 7, female, married, aged 40, admitted Oct 6 as ? meningitis, discharged Nov 9

General Clinical Description

Early symptoms included mild sore throat, lassitude, drowsiness, vomiting, nuchal pain, backache, giddiness, and headache Slight or moderate stiffness was variably found in the neck or in the back, with or without Kernig's sign, but in case 2 these signs were altogether absent In case 6 muscle tone was diffusely increased in the paretic right arm In case 5 spasm developed in the left calf Muscle tone in the affected limbs did not otherwise seem abnormal

Paresis was found in all the cases It was diffuse and tended to fluctuate and shift In cases 1–6 it varied in onset from the first to the fifth day of disease In case 7 there was a history of weakness and clumsiness in the left arm for the preceding 2 months, hindering her domestic activities and occasionally making her drop things (This patient had the blood picture of glandular fever but was apyrexial, small lymphatic glands were palpable in the neck only increase of symptoms with vomiting, severe occipital headache, and slight nuchal rigidity prompted her admission to hospital as ? meningitis) In several cases weakness affected two or three limbs, tending later to predominate in one, in other cases one limb alone was weak The limbs predominantly affected were right leg (2 cases), left leg (3 cases), right arm (1 case), and left arm (1 case) Ability to use a limb ranged from frank immobility to slight reduction in power detectable on careful testing against resistance and accompanied by aching, "heaviness," and undue fatigability Inadvertent muscular action in an apparently paralysed limb was seen in case 1 During recovery case 2 was startled by a transient nocturnal increase of paresis in the legs Complaints were made of "slight cramps," "spidery" or "wormy" sensations, and of a limb disturbing rest by "jumping" Fasciculation was observed in case 3, the patient also complained of transient dyspnœa and intermittent diplopia 3 patients had difficulty in starting micturition, and 1 had incontinence of urine Slow coarse intention tremor was seen in several cases

Tendon-reflexes were brisk and equal Plantar responses were flexor but tended to be feeble and indeterminate in affected limbs The superficial abdominal reflexes were present Paræsthesiæ, diffuse aches, and muscle tenderness occurred In case 1 (see below) cutaneous and deep anæsthesia was found in the paretic limbs generally and an area of hyperæsthesia in one axilla In case 6 hypoæsthesia was found in the affected right arm from mid-forearm downwards together with a degree of astereognosis in the right hand Case 5 had hyperæsthesia over the extensor surface of the upper arms Case 2 complained of photophobia and hyperacusis and vague abdominal tenderness with pain on deep inspiration Several patients complained of diminished mental grasp, which returned in convalescence

No enlargement of liver or spleen was found Small shotty lymphatic glands were palpated in the posterior cervical triangles in cases 1, 3, and 7 (mentioned above) They were smaller, for example, than those of a typical case of rubella Cases 6 and 7 were apyrexial Case 4 had a continued pyrexia (reaching above 103°F) for five days In other cases low intermittent pyrexia (99–100°F) occurred

All the patients were ambulant when discharged after a hospital stay of from eleven days to five weeks All except case 5 were available for follow-up in the third month from admission At this time recovery appeared satisfactory in cases 2 and 3 Aching, "heaviness," or pins and needles in the affected limbs, especially after use was variously complained of by cases 1, 4, 6, and 7 Full power had returned in case 4, but there was slight reduction of power against resistance in case 1 (dorsi flexors of left foot), case 6 (right arm), and case 7 (left arm) A fine tremor showed in the right hand of case 6 after brief exertion, and his right arm, if forced to give way, did so in a cog-wheel fashion

Illustrative Case-record

Case 1 is representative clinically and remarkable in having been admitted for a similar illness in 1953

A married female textile machinist, aged 22, developed a mild sore throat which cleared in two days Three days later she had headache and pain at the nape of her neck, giddiness, lassitude, hot and cold "flushes," aching in her right arm, and difficulty in gripping things, her legs became heavy and hard to lift, and cramps and profuse sweats occurred She lost power in the involved limbs and was admitted as a case of paralytic poliomyelitis

Previous Illness

Three years previously (1953) she had been admitted with a similar history (as were many others at that time) Her legs alone were involved at first, but shortly after admission her recti abdominis muscles became weak, dyspnœa developed and a cabinet respirator was prepared for her She improved, however, and it was not used. Her cerebrospinal fluid (C S F) was normal Within six days some recovery was evident in her abdominal muscles and legs and on discharge a fortnight later she was clinically normal An appointment was made for her follow up but she felt so well that she did not keep it From that time until the present illness she had not complained and did not have any comparable illness Several weeks after her discharge in 1953 cases of a similar kind began to occur among the nurses of the hospital, and in retrospect the original diagnosis of paralytic poliomyelitis was altered to that of an unknown infection simulating that illness

Examination

On admission she was apyrexial, anxious, rational, and coöperative and mentioned that she had had "polio" three years previously She complained of headache, numbness, and inability to lift her right arm and both legs Just before admission the affected limbs had been aching, and she was relieved when this gave way to numbness Slight nuchal rigidity and a positive Kernig's sign were present Abdominal reflexes were elicited but were weaker than normal, and vague abdominal pains were complained of Tendon reflexes were exaggerated Cutaneous sensibility to touch, pain, and temperature and position sense were absent in the right upper and both lower limbs, and firm pressure over the Achilles tendons did not cause pain There was hyperæsthesia in the right axilla The plantar responses were inconclusive Shotty glands were palpated in the posterior cervical triangles Incontinence of urine occurred in the ambulance and twice after admission

Progress

During her stay in hospital the patient had low irregular pyrexia (99 2°F being the highest recorded) Within two days sensation and much power had returned to her arm, next day her left leg was greatly improved, and by the next her right leg had also become normal This was the order in which the limbs had become affected Sensation both superficial and deep was restored, and she could walk unaided She commented spontaneously that her concentration was bad and that she felt depressed although she had not previously been that way inclined Diplopia and "spots before her eyes" were other features and they cleared up within a few days On discharge seventeen days after admission she appeared to have returned completely to normal

Follow up several weeks later showed, however, that there was slight weakness of the dorsiflexors of the left foot when tested against resistance The patient received physiotherapy, and on further follow up two months later weakness was still just detectable, but she was without disability

Investigations

Blood —If 2500 per c mm is taken as the lower limit of normal of absolute numbers of neutrophils (Dacie 1956), 2 patients had neutropenia, 2 others less than 3000 per c mm, and the highest number found was 3068 per c mm In 2 cases occasional atypical lymphocytes were found In case 7 the blood picture of glandular fever was found total leucocytes 5600 per c mm (lymphocytes 35%, atypical lymphocytes 28%, glandular fever cells 28%, monocytes 9%) A month later the glandular fever cells had disappeared The Paul Bunnell test was + 1/128 (after absorption + 1/80, ± 1/160) and later + 1/256 Erythrocyte sedimentation rates and liver function tests were normal in all the cases

C S F —Cell counts and protein and sugar values were normal except for a slight increase of protein in 3 cases (60, 50, and 80 mg per 100 ml)

Electrodiagnosis —Stimulation of the external popliteal nerve in the 5 cases having weakness of the tibialis anticus muscle showed retention of nerve conduction, muscle response being brisk Electromyography with needle exploration of the muscles showed no fibrillation potentials or other signs of spontaneous activity, in all the cases grouping and reduction in number of the motor unit potentials on volition were found Some potentials were polyphasic and often of very large amplitude

Electro encephalography was performed in cases 1, 2, and 3 and was normal in 1 and 3 Case 2 showed a basic alpha rhythm of 10 cycles per sec in the postcentral leads at potentials up to 50 µV This rhythmic activity was disturbed at times by irregular slower activity (about 7 cycles per sec) of low amplitude this being more noticeable in the transverse leads These minor irregularities were deemed to be within normal limits

Virus investigations made in cases 1, 2, and 3 did not reveal the presence of any cytopathogenic agent in the fæces and serological tests for poliomyelitis were negative

Discussion

These 7 cases, though resembling those seen in the outbreak of "poliomyelitis like illness" in Coventry in 1953, were less severe than some in that year The kaleidoscopic clinical picture did not hide their similarity to each other Laboratory investigations were, as in 1953, largely unrewarding, but case 7 showed the hæmatology of glandular fever Neurological complications occasionally develop in glandular fever (Fullerton and Smith 1951), but in this case it seems likely that the weakness in the left arm (of two months' standing) preceded the mononucleosis Bowie (1954) regards sporadic glandular fever as a syndrome occurring in people appropriately sensitised by a previous infection and reinfected "with the same or a closely allied organism" 2 other patients had atypical lymphocytes In the C S F the cytology was normal, but in 3 patients the protein content was a little increased As in all previously reported series virus investigations were negative

Electromyography was abnormal in all the cases, recalling that of the Coventry outbreak in 1953 and that described by Ramsay and O'Sullivan (1956), who compare their findings to the so-called myelopathic pattern of early motor involvement at cord level described by Bauwens (1955) Nevertheless the characteristic clinical or electrodiagnostic picture of lower motor neurone degeneration did not develop as in prolonged paralysis in paralytic poliomyelitis, and, in the 3 cases so tested nerve conduction remained good

Electro encephalograms were obtained in 3 cases, although these were all within normal range, 1 showed minor irregularities similar to those mentioned by Ramsay and O'Sullivan (1956)

The anomalous clinical picture and negative or minimal laboratory findings in some instances aroused suspicion of hysteria Against this is the cumulative weight of such considerations as the underlying consistency in the clinical picture, the local prevalences, the lack of general correlation with the hysterical temperament, the pyrexia of some patients and the abnormal electromyographic findings The latter are of particular value in confirming the presence of an organic lesion (*Lancet* 1956)

Summary

5 cases of suspected paralytic poliomyelitis, 1 of suspected meningitis, and 1 of pyrexia of unknown origin admitted to a Coventry hospital in 1956 provided grounds for a diagnosis of "benign myalgic encephalomyelitis" One patient had had a similar illness in 1953 In another patient there was laboratory evidence of glandular fever Electromyography gave in all the cases an abnormal pattern with grouping of action potentials

Our thanks are due to Dr J Shulman, of the Coventry and Warwickshire Hospital, for the electrodiagnostic investigations and comments, to Dr C Tetlow, of the Central Hospital, Warwick, for the electro encephalograms and comment, to Mr J H Penrose, of the Coventry and Warwickshire Hospital for the orthopædic report on case 5, to Dr W C M Wilson and Dr W Davie, of the Coventry Joint Laboratory, for biochemistry and hæmatology, to Dr A D Macrae of the Virus Reference Laboratory, Colindale, for virological and Dr R Ewart Jones, of the Coventry Public Health Laboratory, for bacteriological investigations, and to Dr A Melvin Ramsay, of the infectious diseases department and Dr A T Richardson, of the department of physical medicine of the Royal Free Hospital, for their most helpful advice

SURGICAL TREATMENT OF LARGE AIR CYSTS OF THE LUNG

L. H. CAPEL
M.B. Lond., M.R.C.P.
SENIOR REGISTRAR, LONDON CHEST HOSPITAL

J. R. BELCHER
M.S. Lond., F.R.C.S.
SURGEON, LONDON CHEST HOSPITAL; ASSISTANT THORACIC SURGEON, THE MIDDLESEX HOSPITAL, LONDON

> " . . and if the air blown into any lobe will not be expelled thence by the natural tone or muscle of the bladders, that the lobe may again subside of itself, 'tis certain that some injury is done to the ventiducts; the bladders are either broken, and admit air into the membranous interstices, or else they are over distended like a hernia in the peritoneum; and this will produce an inflation of the whole substance of the lungs, and that a continual compression of the air and blood vessels, which will produce a constant asthma."—Sir JOHN FLOYER, *Treatise of the Asthma*, 1698

Sir John's account of the development of "windy tumours" in the lungs cannot, except in details, be greatly improved upon today.

Air cysts of the lung are not common. They may be small or they may fill one side of the thorax. However large they are, the disability they cause may be negligible or it may be severe. When disability is present, it is uncertain how much of it is due to the cyst, how much to associated lung disease, and how much to the combined effect of the two. It is not known whether the cysts will get bigger or not. These uncertainties and the severe breathlessness of some of the patients have made surgeons and physicians reluctant to advise surgical treatment.

We believe that the success attending surgical treatment of carefully selected patients with large cysts of the lung is not sufficiently well known. This may be because the number of reports of cases so treated is small. Ten authors have described surgical treatment of a total of 88 patients, resulting in "improvement" in 82 (Abbott et al. 1953, Allbritten and Templeton 1950, Clagget 1949, Cook and Blades 1952, Crenshaw and Rowles 1952, Dugan and Samson 1950, Head and Avery 1949, Naclerio and Langer 1947, Santy et al. 1955, Weisel 1955). None of these authors give precise indications for the selection of the individual case for treatment. We will describe the surgical treatment of 21 adults with large air cysts of the lung, and we will try to show how those patients for whom the operation is both necessary and reasonably safe may be selected from the clinical and radiological findings.

Diagnosis

Diagnosis of air cyst of the lung may be made by radiological examination alone. The cyst may be discovered unexpectedly following inspection of the chest radiograph of a patient diagnosed as suffering from "chronic bronchitis and emphysema" because he complained of chronic productive cough, breathlessness, and wheeze. It may be seen on the radiograph of a patient with spontaneous pneumothorax. Occasionally it is seen on the routine film of symptom-free people.

The clinical and radiological findings in our patients are summarised in table I. Most of the patients had been breathless for many years. Spontaneous pneumothorax was common.

The radiograph of the chest showed the cyst, sometimes mediastinal shift, sometimes herniation across the anterior mediastinum, and usually evidence of disease in the rest of the lung. The cyst was located by abnormal radiolucency caused by the absence of vascular shadows and by the smooth outline of the cyst wall. Sometimes a thin cyst wall was difficult to see even on tomograms. Often it was better seen on the lateral film or on a film taken in expiration.

Bronchograms sometimes helped to define the limits of the cyst. They showed compression of the lung and distortion of the bronchi around the cyst. They gave some information about the health of the rest of the bronchial tree. Bronchograms are a great help in making the occasionally difficult distinction between a large cyst and spontaneous pneumothorax. Our experience has been that where the diagnosis was in doubt the lesion was a large cyst.

During fluoroscopy, the cyst and more obstructed parts of the lung darkened (emptied themselves of air) slowly or not at all during forced expiration. In some cases where obstructive lung disease was much more advanced in the lung with the cyst, the mediastinum swung to the sounder (less obstructed) side. This swing was better seen with a column of barium in the œsophagus. General obstructive lung disease was accompanied by slow and incomplete darkening (emptying) of the whole lung field and slow and limited movement of the domes of the diaphragm.

Fluoroscopy used in this way gave an indication of the severity and distribution of obstructive lung disease. We were able thus to make a rough guess at the contribution of each lung to total ventilation. It was established that the side of the chest to be opened in each patient was doing less than half of the total ventilation. In 8 cases bronchospirometry was used to confirm this.

Selection for Operation

All the patients chosen for operation were breathless. Their cysts occupied at least a quarter of one lung

TABLE I—CLINICAL, RADIOLOGICAL, AND SPIROMETRIC FINDINGS

Case	Age	Sex	Effort tolerance		Sputum		No. of spontaneous pneumothoraces	Cyst size	Forced expiration volume (c.cm. in 1 sec.)	Vital capacity (c.cm.)

* Maximum breathing capacity (litres per min.)

Sputum: + = an egg-cup a day; + + + + = a cup a day.

Duration: Time in years since symptoms of effort intolerance or expectoration first appeared, irrespective of severity.

Effort tolerance grade:
0 = No disability
1 = Cannot hurry on hills
2 = Cannot hurry on level
3 = Cannot keep up with others on level but can walk any distance own speed
4 = Cannot walk 500 yards or 20 min. slowly
5 = Cannot walk 100 yards or 5 min. slowly
6 = *Bedridden*

The horizontal line separates those with a cyst occupying half or more of one lung field (above) from those with a cyst occupying less than half of one lung field (below).

field on the radiograph In 3 patients repeated spontaneous pneumothorax was the main indication for surgery Breathlessness, however, severe, was never alone a contra indication

A number of patients with cysts occupying more than half of one lung field were refused operation because they were not breathless

Only 1 breathless patient with a large cyst was refused operation On fluoroscopy the cyst was found to be on the better ventilated side, and this was confirmed by bronchospirometry The other lung had been severely damaged by pneumonia Operation may be reconsidered should breathlessness become more severe

The Operation

Anæsthesia

To prevent dangerous expansion of the cyst and further embarrassment to the lungs "positive-pressure" ventilation was not used until the chest was opened An attempt was made to keep the partial pressure of alveolar carbon dioxide near that to which the patient was accustomed Hypoventilation might exaggerate the carbon dioxide retention which was already present Hyperventilation may so far reduce the partial pressure of carbon dioxide in the blood that spontaneous breathing may be slow to re establish itself (Atherstone 1956)

Surgical Details

A posterolateral approach was used in all save 1 patient in whom cavity drainage was performed When the chest was opened, an attempt was made to assess the condition of the whole lung Often before this could be done the cyst had to be incised because the lung was so voluminous that it herniated through the wound as soon as the pleura was opened Two anepithelial cysts (Belcher and Siddons 1954) were encountered in this series, in these the blood supply was ligated and the cyst was removed intact In 1 case, cavity drainage as recommended by Head and Avery (1949) was established in two stages and the tube was left in situ for a long period In the remaining 18 patients, cysts and a varying degree of emphysema were found Where one or more cysts were present and particularly where the lobe concerned appeared to contain areas of normal alveoli the procedure described by Naclerio and Langer (1947) was carried out the visceral pleura which formed the outer wall of the cyst was removed, the air leaks from the underlying lung were sought and oversewn, and the raw areas were approximated This was done on eight occasions On the other hand, where the whole lobe was destroyed by generalised alveolar breakdown, where all the intersegmental planes were disrupted, and where it was possible to express air from one end of the lobe to the other, resection was carried out One segmental resection, eight lobectomies, and one pneumonectomy were performed

As it was felt that these patients were suffering from mechanical rather than from nervous or reflex disorders, the vagotomy recommended by Abbott et al (1950) was not carried out

Postoperative Care

Drainage tubes were used in all cases and continuous suction was applied at once In most patients there was a considerable air leak from the cut lung surfaces in the period immediately after the operation In only 1 patient did it persist for more than a few days In this case an empyema which developed was successfully treated by simple drainage In the remainder the tubes were removed on an average five days (maximum nine) after operation

To reduce the risk of carbon dioxide narcosis, oxygen was not given as a routine and heavy sedation was avoided Only 1 patient, treated early in the series, died shortly after operation The lung on the unoperated side was too diseased to support life by itself In no other case was there any cause for alarm

Results

Of the 21 patients treated, 9 were enormously improved and 8 claimed moderate or slight improvement (*table II*) All who claimed improvement said they were last as well between three and fifteen years ago 1 patient died four days after operation before operation he had been breathless even in bed, and both lungs had been severely damaged by disease A large cyst was present

Grading and volumes as in table I * Maximum breathing capacity (litres per min)
† E = enormous improvement M = moderate improvement S = slight improvement

1 Died following spontaneous pneumothorax on other side some months after operation
2 Died four days after operation
3 Died some months after operation of unknown cause following initial improvement
4 Died from glioma some months after operation
5 Cavity drainage

The horizontal line separates those with a cyst occupying half or more of one lung field (above) from those with a cyst occupying less than half of one lung field (below)

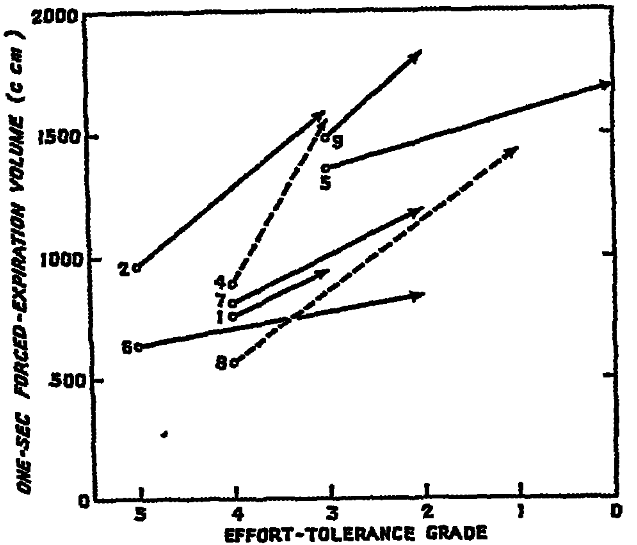

Fig 1—Change in effort tolerance grade and one-second forced-expiration volume after removal of lung cyst Second measurements made about three months after operation Broken line indicates that forced-expiration volume is calculated from M B C Case numbers correspond to those in table II

on each side The efficiency of the lung on the unoperated side had been overestimated

3 other patients died, none as a result of operation 1 with severe hypertension died from an unascertained cause six months after an operation which had been followed by considerable initial improvement A patient with severe hypertension but few symptoms was operated on because of recurrent spontaneous pneumothorax he became worse with hemiplegia and died two years later from a spontaneous pneumothorax on the unoperated side 1 patient whose condition was unchanged by the operation died later from a brain tumour

Assessment of Results

Change in effort tolerance—Change in effort tolerance is the best way of assessing the value of an operation intended to improve it An attempt was made to assess effort tolerance from the answers to standard questions put to the patient before and after operation Effort tolerance was then graded as in table I In 15 patients, including the 9 who claimed "enormous improvement," their grading was roughly confirmed This was done by one of us walking with them before and after operation, on the level and up stairs The changes experienced by the patients are shown in table II Those we considered "enormously improved" are indicated

Change in lung function—Objective evidence of any change in lung function which might be associated with any change in effort tolerance was sought from timed ventilation studies (table II) The change in one second forced expiration volume seen in tests before and after operation have been graphically related to the change in the effort tolerance grade after removal of the cyst in 8 of the 9 patients who claimed enormous improvement (fig 1) The increase in timed expiration volume is seen to be related to the increase in effort tolerance This was independent of season

Change in bronchial disease—6 of the patients claiming "enormous improvement" regularly brought up large amounts of sputum (an egg cup to a cup a day) before operation Since operation 5 of them bring up less than an egg cup a day, except after head colds The 6th patient reports no change in the quantity of his sputum All patients who "improved enormously" noticed a big reduction in their wheeze, and this is confirmed by the improvement in one second forced expiration volume

Improvement in well-being—The patients who enjoyed an improvement in effort tolerance also reported an improvement in well-being Here are typical expressions of this

"Much more energetic Last as well five years ago"

"Much better My ankles do not swell any more"

"Life worth living now I used to see my doctor every week Now I haven't seen him for a year, except socially"

"Was suicidal for two years My depression now gone More buoyant Last as well ten years ago"

"Sputum much less Surprise my wife by going to sleep without a wheeze"

"No comparison, a different man now Even acquaintances notice the improvement Can run for a bus now Have not done this for three years '

"Twice as fit Last as well ten years ago Much more energy Circulation much better Hands and feet no longer get cold"

"For five years *I could not walk more than one hundred yards* without a stop Before I left hospital I was able to run upstairs with less trouble than the physiotherapist Circulation much better Hands and feet do not now get so cold"

"They've got my wheeze upstairs," (i e, in the operating-theatre)

Weight change—In 8 patients there was simple objective evidence of this improvement in well-being They gained at least one stone in weight during the six months following operation This was maintained on leaving hospital

Effect of cyst size on the result—All the cysts occupied more than a quarter of one lung field on the radiograph 12 patients had cysts occupying a half or more than a half of one lung field 9 of these 12 patients with the bigger cysts were the ones who "benefited enormously"

Disability before operation—Only 3 patients had little disability before operation Repeated spontaneous pneumothorax was the reason for operating on them The rest were disabled, some severely (see table I) None of these patients were able to walk at a normal pace 7 were unable to walk a hundred yards 7 patients were able to blow between 450 c cm and 1000 c cm only in the first second of forced expiration This might be compared with maximum breathing capacities in the range 15–30 litres a minute The remarkable improvement experienced by some of the most disabled will be noticed (table II)

Follow-up—All patients were followed up for at least three months 4 were followed for one year and 5 for two years or more In all cases where it occurred "enormous improvement" in effort tolerance and well-being was noted soon after operation—within three months In all cases this improvement has persisted apart from temporary setbacks in bad weather and during bronchial infection

Timed ventilation increases were at their maximum about three months after operation Most of our recent follow-up measurements are lower than the maximum values About half the gain has been lost, but this may be due to winter We have not yet been able to complete our study of weather and time change We believe this fall may prove too big to be explained by weather changes alone

DISCUSSION

The disability in patients with large air cysts of lung is due to mechanical interference by the cyst with the ventilation of diseased lungs The cyst and lungs are too big for the thorax As soon as the chest is opened the cyst balloons through the incision The anæsthetist immediately notices an improvement in the patient's condition and ventilation This has often been reported (Atherstone 1956, Dugan and Samson 1950)

Compression may prevent ventilation of relatively healthy lung near the cyst Respiratory effort is wasted in changing the volume of the cyst The existing tendency of the damaged lungs to trap air is increased Some of the tidal volume is lost to the ventilation of the cyst

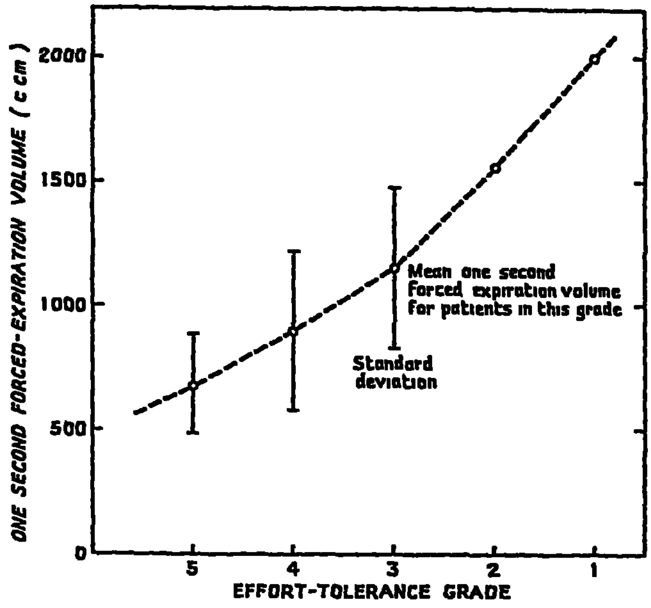

Fig 2—Relationship between effort-tolerance grade and one-second forced expiration volume in 150 patients with chronic obstructive lung disease

The bronchial leak into the cyst was found at operation to be fairly large in some patients and small in others

If the lungs are healthy, a cyst may encroach on two thirds of one lung field and the patient yet be symptom-free Breathlessness, when present, must therefore be related to general disease of the lungs The more diseased they are the less are they able to carry the extra burden of the cyst It follows that the larger the cyst and the more breathless the patient, the more seriously must operation be considered. Our experience has confirmed this

2 patients with very large cysts (half of one lung field) but no symptoms were tested Timed ventilation measurements were almost normal in one and about two thirds presumed normal in the other There is no evidence that the disease is progressive in these patients Even should they deteriorate nothing is lost by waiting

As, over the years, diseased lungs gradually lose their efficiency, there comes a time when small deteriorations cause disproportionately large losses of effort tolerance The mean difference in one second forced-expiration volume between normal people and our grade 3 patients (those unable to walk with others on the level but able to walk any distance) is 2500 c cm The mean difference between our grade 3 and our grade 5 (patients unable to walk one hundred yards slowly) is only 450 c cm This difference was found in a study of over 150 patients with bronchial disease in our laboratory

Similarly, it would be expected that small increments of lung efficiency, signalled in our patients by small increments in the one second forced expiration volume, might be followed by a disproportionately large improvement in their effort tolerance This, we believe, explains in part the "enormous improvement" enjoyed by our 9 patients

In 150 patients with bronchial narrowing or obstruction as a feature of their chronic lung disease, we have compared their effort tolerance graded as described (table I) with their one second forced expiration volumes (Smart and Capel 1957) There was a clear relationship between the two (fig 2) In 8 of our 9 patients who "improved enormously" the increase in one second forced expiration volumes for the increase in effort tolerance grade claimed by the patient was what would have been expected if this relationship held true for them This suggests that the improvement is proportional to the relief of airway obstruction

As we believe the disability to be due to mechanical interference with lung ventilation, we see no place for pulmonary plexectomy in treatment Those who have reported most benefit from this manœuvre found it largely in those patients from whom the cyst had been removed as well Their reported improvements with plexectomy seem to be comparable to ours without it

The comparative safety with which these often dangerously disabled patients may be operated on is not unexpected The patient with respiratory insufficiency is never so well off as he is temporarily during the controlled ventilation of anæsthesia The patient with a large cyst improves as soon as his chest is opened The operation is technically fairly simple A critical burden is removed so increasing the patient's ventilation reserve Our "enormously improved" patients claimed benefit even during the first few days after operation

Conclusions

As radiological diagnosis may be difficult, a close study should be made of the chest radiographs of all breathless patients before they are labelled "chronic bronchitis and emphysema"

In 8 of the 9 patients who were "enormously improved" there was direct and indirect evidence that this improvement was related to relief of chronic obstruction of the airways It may be that the presence of a large cyst in the thorax can aggravate the general narrowing of the bronchi of lungs already diseased

Surgery should not be considered in symptom-free patients Resection is dangerous in very breathless patients when fluoroscopy (and bronchospirometry if available) show the cyst to be on the more efficiently ventilated side of the chest Open drainage may be proved to be of value in these cases

Surgery should be considered in all breathless patients who are found to have an air cyst of the lung occupying at least a third of one lung field on the chest radiograph The larger the cyst and the more breathless the patient the more urgently is surgery required

Summary

(1) 21 patients with large air cysts of the lung (occupying more than a third of one lung field) were treated surgically

(2) Clinical and spirometric findings before and after operation were recorded

(3) The operation proved both simple and safe

(4) 9 of the patients were "enormously improved"

(5) It is concluded, with one reservation that the larger the cyst and the more breathless the patient the more seriously must operation be considered

We wish to thank Dr J Smart for his advice, for his assistance with the pulmonary function studies, and for referring patients to us We also wish to thank the other physicians who referred patients

RECTAL BIOPSY AS AN AID TO THE DIAGNOSIS OF AMŒBIC DYSENTERY AND ALLIED DISEASES OF THE COLON

Sir Philip Manson-Bahr
C M G , D S O , M D Camb , F R C P
CONSULTING PHYSICIAN, THE HOSPITAL FOR TROPICAL DISEASES, LONDON
W J Muggleton
M S M , F I M L T

In the routine diagnosis of dysenteriform diseases, which falls to the lot of the tropical physician, it is advisable to have as many strings to one's bow as is possible

It is a fact that, generally speaking, little crucial information can be garnered either from the patient's history or from physical examination of the abdomen In patients hailing from the East, in whom a whole series of differing diagnoses have been made from time to time, and an equal number of varying treatments prescribed, it is a recurrent perplexity to disentangle the probable course of events So often the diagnostician is faced by the same story of repeated fæcal examinations positive for amœbæ one day and negative the next—a discrepancy which has given birth to the widespread and popular belief that the causal organism disappears from the intestinal tract directly the patient passes from the tropics to temperate zones, only to reappear in reinforced numbers immediately on his return to the endemic areas If the fæces contain no active amœbæ or cysts, little will be gained from even the most skilful microscopic examination of them

In consulting practice, it is not possible to admit to hospital for long and elaborate laboratory tests every patient who complains of an intestinal upset It is therefore desirable to devise a technique whereby a positive and reliable diagnosis may be arrived at with the minimum expenditure of time In this paper we describe the method we have routinely used for the past few years, and broadly summarise the results obtained. We are encouraged to do so by the success of this technique

The diagnosis of amœbic dysentery may be very simple, on the other hand it may be and often is, the very reverse *Entamœba histolytica*, in its habits may be likened to a Scarlet Pimpernel of tropical medicine—" here today and gone tomorrow " It is this cyclical appearance of the organisms which renders routine diagnosis such a chancy affair Because of the sporadic nature of the infection and its confinement for the most part to the large intestine, no reliable intradermal or serological diagnostic tests have been evolved, and the diagnosis ultimately depends, therefore, on identification of the causative organism In such diagnosis the discovery, in a preparation, of one authentic *E histolytica* is as important as that of a dozen or more

Rectal Biopsy

The sigmoidoscopic appearances of amœbic lesions on the bowel will have been often described In the acute stage they are often obvious and characteristic, but in the chronic stage they may be difficult to detect In some cases the points of entry into the mucosa are so minute as to escape detection and in others active and typical amœbæ have been identified in preparations from the normal mucosa From the diagnostic viewpoint it is fortunate that *E histolytica* is a parasite of the large intestine and is apt to favour the lowest part of the bowel—the rectum in particular The lesions are therefore readily accessible, and through the proctoscope biopsy scrape preparations are easily and painlessly obtainable The rectum proper extends for 5 in , of which $4\frac{1}{2}$ in can be viewed through the proctoscope

The technique is simple, and skill in its application is readily acquired The instrument used does not conform to the common model designed for the treatment of hæmorrhoids or examination of the lower bowel, but has been designed for this specific purpose It is a tubular rectoscope, 6 in in length by $\frac{5}{8}$ in in diameter, and is provided with a suitable handle

After lubrication with ' K-Y Jelly ' (*not* petroleum jelly which tends to spoil the preparation), the tube, which has previously been warmed in water, is inserted and gently pushed up so as to permit examination of $4\frac{1}{2}$ in of the rectum The importance of pushing the instrument home lies in the fact that the part of the mucous membrane coming into contact with the end of the tube bulges into it, presenting a suitable surface for biopsy scraping An area of the mucosa can be viewed at the upper limit of the tube range, and other areas as the instrument is being slowly withdrawn For illumination a dental lamp provides a full, evenly distributed illumination and is known as the ' Straight Illuminator Lamp ' It is fitted into a long flex attached to a battery It is not necessary as a routine to use a magnifying eyepiece

Biopsy material is obtained by scraping the suspected area of the mucosa with a long handled Volkmann spoon The stem is 16 in in length and the diameter of the cup $\frac{1}{2}$ in It is important that the edges of the spoon should not be so sharp as to unduly lacerate the tissues A sample of the diseased mucosa is obtained by side-to-side movement of the base of the spoon impinging against the interior of the proctoscope By these means a definite slice of the mucosa comes to lie in the hollow of the spoon this is removed directly, with the aid of a matchstick, on to a microscope slide, and a " squash preparation " is produced by pressing down with a no 1 $\frac{3}{4}$-in -square coverglass

The specimen is first quickly examined under a low-power lens and then with the $\frac{1}{6}$ in It is essential that the microscope should always be handy, for the preparation *must* be fresh and *the cells must be seen in the living state* An interval of 5–10 minutes is fatal to success since the finer appearances of the mucosal pattern deteriorate with great rapidity *No normal saline or other diluent should be added* The addition of vital stains do nothing to assist in the interpretation of the appearances which must be assessed with the tissue in a fresh and undamaged state The condenser should be racked down so as to be able to obtain clear definition of the outlines of the intestinal cells

Macroscopic Appearances of Amœbic Lesions

In the main the lesions of amœbic dysentery seen in the rectum conform to those seen higher up in the sigmoid colon

In the acute stage, small, discrete, flat depressions, with undermined edges and hæmorrhagic margins, can be distinguished Submucous telangiectatic hæmorrhages are often seen in their vicinity In our experience it is rare to be able to recognise the classical diamond shaped amœbic ulcer in this situation More usually the changes are very superficial and range from small granulations to hyperæmic patches

In the chronic stage the changes are so minute and so superficial that they may escape detection The actual depressions in the mucosa may be so shallow that it requires oblique illumination, as Cropper (1945, 1951) has emphasised, to show them up By punch biopsy he has shown that the cavity of such a lesion extends down to the muscularis mucosæ beneath the superficial glands In 1937 one of us (P M -B) described the mucosa as " pock marked " and as resembling the lesions produced by the nibbling of " microscopic mice " (fig 1) It is to Cropper that we are indebted for the expressive terminology in which he compares the pin-point craters to those of bomb craters as seen in aerial photographs The small ones upon which we place particular emphasis give what he terms a "pigskin appearance" or minute scattered pits, resembling pinpricks on a plasticine surface Cropper has demonstrated their microscopical structure by "punch" biopsy It is necessary to differentiate this pathological picture from the regularly disposed openings of Lieberkühn's *glands in the lower* rectum

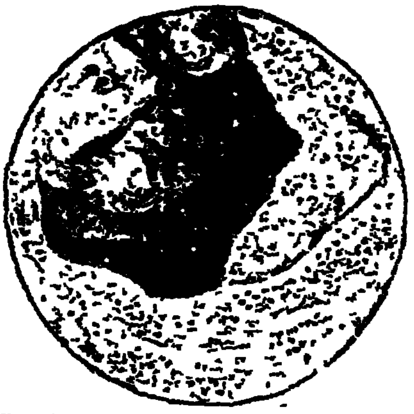

Fig 1—Proctoscopy of rectum chronic amœbic dysentery "Pigskin pittings"

Microscopic Appearances in Scrape Preparations

The Normal Picture

A preparation of normal mucosa shows the crypts of Lieberkühn with their contained columnar cells spread out in a symmetrical mosaic pattern when spread out on a slide (fig 2) The boundaries of the glands can be envisaged outlined with capillary vessels and encompassing (besides the normal cells) goblet cells, lymphocytes, and occasionally eosinophils

Amœbic Lesions

In biopsy scrapings under the microscope, *E histolytica* in the active and cystic stage can readily be picked out from the midst of the necrotic debris by its refractile and shiny appearance (fig 3) There is something crystalline about it which makes it stand out, so to speak, from the surrounding cells To make recognition absolutely certain, the organisms should protrude pseudopodia and perform amœboid movements They can easily be induced to do so by warming the slide (No elaborate apparatus is necessary, placing the slide for a few minutes on the microscope lamp base suffices) We would draw attention to the fact that cysts of the non pathogenic amœbæ, such as *E coli*, *E nana*, and *Iodamœba butchlii tend to adhere* to the mucosal surface and may be demonstrated in this situation We have also found therein ova of ascaris ancylostoma, *Schistosoma mansoni*, *Tænia saginata*, and oxyuris, besides adults of the latter worm

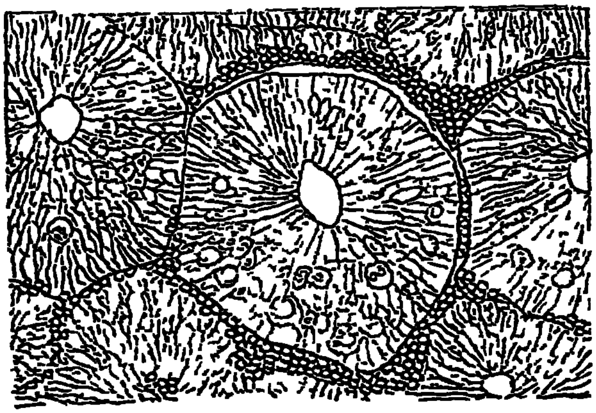

Fig 2—Normal rectal mucosal pattern

Bacillary Dysentery

A recurrent difficulty in tropical practice is the differentiation of mild attacks of bacillary dysentery from those of the amœbic form, and to obtain some positive evidence as an aid to treatment For this purpose the history and physical examination, however thorough, may yield remarkably little information Microscopical examination of the fæces may also provide little, and cultural methods are on the whole too long, too tedious, and too uncertain, while serological reactions are subject to the same drawbacks and are usually unreliable

The proctoscopic appearances of these post-bacillary cases are superficial and slight Usually the mucosa has an angry and lack-lustre appearance at the most small, deep red, strawberry-like granulations are visible On the other hand, the cellular changes in biopsy preparations are very helpful to the trained eye The diagnostic sign consists in the recognition of minute granules in the columnar cells They are of a protein nature, and are coarser and more irregularly disposed than the finer ones only detectable under the $^1/_{12}$ in lens in normal biopsy preparations Frequently, too, small necrotic foci within the crypts of Lieberkühn may be demonstrated (fig 4) These intracellular changes are not found in amœbic dysentery

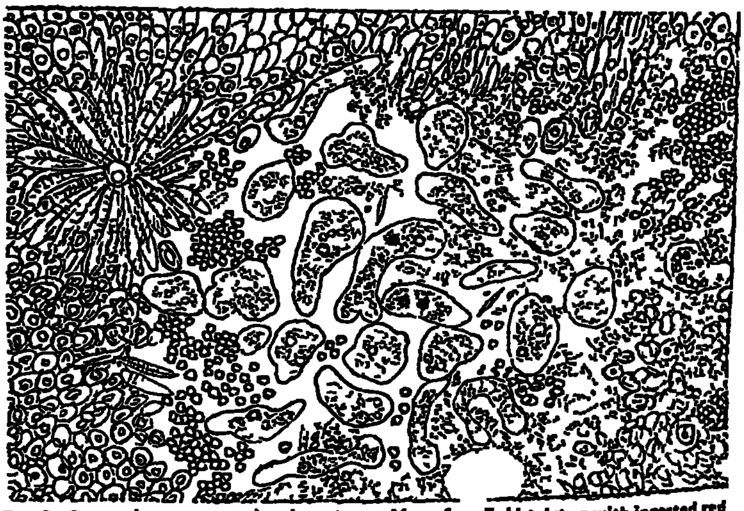

Fig 3—Scrape biopsy amœbic dysentery Many free *E histolytica* with ingested red cells and Charcot-Leyden crystals in a case with no amœbæ or cysts in the fæces

Ulcerative Colitis

It is not always easy to separate the mucosal lesions of ulcerative colitis from those of the bacillary dysenteries We have come to regard the deep red-porter colour of the granulations and the general angry look of the mucosa as being suggestive In biopsy material the picture is that of advanced coagulative necrosis of the crypts and contained cells, together with aggregations of leucocytes and macrophages (fig 5) We have also observed on one occasion a curious phenomenon of autolysis of the cells under the high power of the microscope This consists of minute spirochæte like filaments, undergoing active undulating movement and breaking down into minute granules as depicted in fig 6 This seems to indicate a necrotic process which is peculiar to ulcerative colitis It is possible that this phenomenon can be demonstrated solely in fresh preparations Our experience agrees with the statement that the essential lesion of ulcerative colitis, as seen in rectal biopsy material appears to be an excessive destruction of undifferentiated cells leading to secondary infection (Lumb and Protheroe 1953) The "strawberry lesion" of Shera (1955), confirmed by Thomas (1956), is in our opinion indistinguish

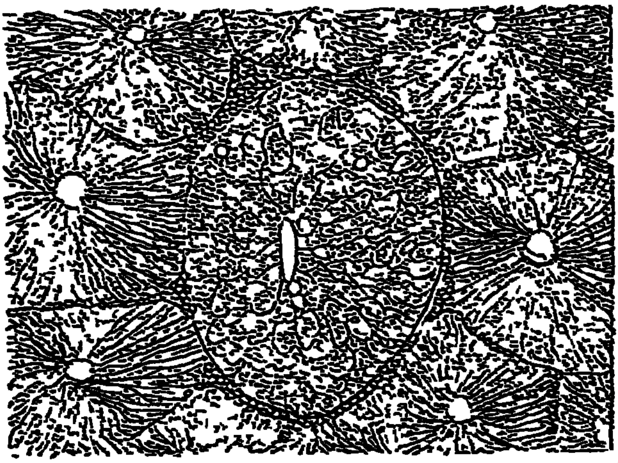

Fig 4—Rectal biopsy showing granular cells in a convalescent case of bacillary dysentery

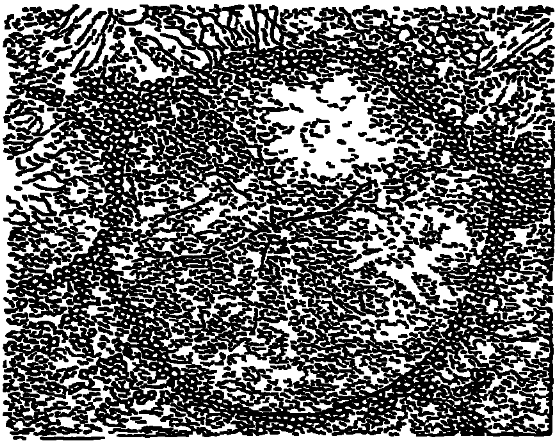

Fig 5—Rectal biopsy showing necrosis and autolysis of cells in acute ulcerative colitis.

able from that of ulcerative colitis with a superadded spirochætal infection In this connection we would draw attention to the appearances illustrated in fig 6, which though obviously of protoplasmic origin bear a close resemblance to massed spirochætes

Mucous Colitis

This and other forms of disturbance of colonic function associated with oversecretion of mucus are often met in the diagnosis of the dysenteries. Here the proctoscope reveals a pale and puckered mucosa overlaid with a patina of adherent mucus In this condition biopsy preparations are very helpful in firmly establishing diagnosis The hypersecretion of mucus can readily be seen in the goblet cells of the follicles, which are swollen with mucin and present a characteristic picture which in our opinion, is reliable in this common condition (fig 7)

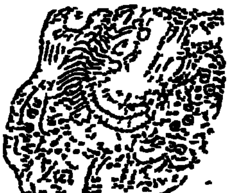

Fig 6—Autolysis of cells of Lieberkühn in acute ulcerative colitis producing an appearance resembling massed spirochætes

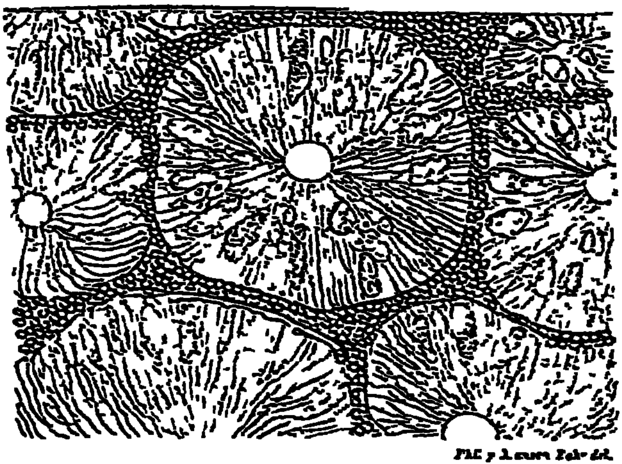
Tropical Sprue

Though the diagnosis of tropical sprue can usually be reached from a physical examination of the patient, from examination of the blood-cells and from analysis of the fæces proctoscopy provides very considerable assistance, especially in borderline cases The mucous membrane has a dull surface and is usually pale rose pink When mopped with a cotton-wool swab, the surface is not easily damaged (as it is in bacillary infections) and presents a fine beaded surface Usually pale cream-coloured fæces can be seen adherent to the mucosa Biopsy scrapings usually show a regular mucosal pattern, but small nests of fine granules are visible between the crypts, possibly indicating the presence of some mild toxic agent



[illegible]

Fig 7—Rectal biopsy pattern of mucous colitis showing excessive secretion of mucus by goblet cells in the crypts

Amœbic Dysentery . Value of the Method

To compare the microscopical findings in direct examination of the fæces and in proctoscopic scrape preparations we present 30 positive consecutive cases of amœbic dysentery. In these the infection was acquired in the following places

British Guiana 1, Burma 3, Ceylon 1, Egypt 3, England (indigenous case) 1, Far East 2, Iraq 3, India 6 Indo China 1 Italy 2 Malaya 1, Natal 1, Pakistan 1, Venezuela 1, West Africa 3

Examination of the fæces showed *E histolytica* cysts in 16 cases vegetative forms in 5, and both in 2 No amœbæ or cysts were found in 7

In all 7 cases with negative fæces active vegetative *E histolytica* were found in proctoscopy scrape preparations In these 7 there was a previous history of amœbic dysentery in 4, previous diarrhœa and abdominal discomfort in 2, and no previous history of dysentery or diarrhœa in 1

Proctoscopic scrape preparations from the 30 patients showed active vegetative forms of *E histolytica* in 13 and cysts in 2 In 24 of the patients proctoscopy showed the typical red, inflamed or pitted mucosa In 6 the mucosa looked normal, 2 of these exhibited vegetative forms of *E histolytica* in scrape preparations

Of the 30 patients, 15 gave a previous history, or presented positive signs and symptoms, of amœbic dysentery, and 8 of previous or present diarrhœa In 7 there were no previous or present symptoms or signs of diarrhœa or dysentery

The special proctoscope is made by Messrs. Vann Bros the lamp by Messrs John Bell & Croyden, and the Volkmann spoon by Messrs Allen & Hanburys

THIRTY-MINUTE SCREENING TEST FOR PHÆOCHROMOCYTOMA

D Hingerty
M Sc, PhD NUI, A R I C
From the Department of Biochemistry and Pharmacology, University College, Dublin

The estimation of urinary catecholamines is now generally accepted as the most reliable diagnostic test for phæochromocytoma, being more specific (and involving less inconvenience and risk to the patient) than the provocative tests and tests with adrenolytic agents sometimes used

The normal urinary excretion of catechols by resting patients is about 15–30 µg per 24 hours, of which about 80% is noradrenaline (Von Euler 1955), excretion by people engaged in normal daily activities is about twice as high Goldenberg et al (1954), in a study of thirteen normotensives and thirty five patients with essential hypertension, found that it was never more than 100 µg , other workers, however, have reported somewhat higher normal values, the extreme range being 15–185 µg (Burn 1953, Pekkarinen 1954, Von Euler and Floding 1955)

In cases of chromaffin-cell tumours a striking increase is seen Although a 24 hour urinary excretion of only 190 µg has been reported by Goldenberg et al (1954) and one of 180 µg by Burn (1953), the amount excreted is usually about 10–100 times the normal and may be as much as 9000 µg —representing a secretion of about 200 mg per day (Von Euler 1955) The increase is most often in the noradrenaline, though cases have been described in which adrenaline secretion was also greatly increased (Holton 1949, Engel and Von Euler 1950, Goldenberg and Rapport 1951, Burn 1953, Von Euler and Floding 1955)

Several methods (Engel and Von Euler 1950, Lund 1952, Goldenberg et al 1954, Pekkarinen 1954, Moulton and Willoughby 1955, Von Euler and Floding 1955) are now available for estimating urinary adrenaline and noradrenaline For various reasons these are beyond the scope of the average hospital laboratory The semi quantitative method described here, based on the Lund (1952) procedure for separating catechols and developing fluorescent products with ferricyanide (Ehrlen 1948), is designed to detect the presence of more than 180 µg of catechols in a 24 hour collection of urine, without differentiating them as noradrenaline and adrenaline The test can be carried out in about half an hour and can be used as a routine test in any laboratory having an ultraviolet lamp Several specimens can be tested at once with little extra expenditure of time or effort

Procedure

Measure a tenth of the 24 hour collection of urine (filtered if necessary) make up to 200 ml with distilled water, and pour into a 250 ml beaker Add 2 g of aluminium oxide (this need be weighed only once and can be measured subsequently by volume with a small graduated cylinder) and 0 5 ml of 1% phenolphthalein, then add 20% NaOH drop by drop stirring thoroughly with a thick glass rod until a definite pink colour persists (pH about 8 4–8 5) Continue stirring for about a minute, then allow the aluminium oxide (with adsorbed catechols) to settle (The heavy aluminium oxide sediments very rapidly, and no centrifuging is necessary at this stage)

Pour off the supernatant fluid and precipitated phosphate (most of which remains suspended in the supernatant) as completely as possible without disturbing the aluminium oxide, then wash by adding about 200 ml of distilled water, stirring allowing to settle and pouring off the water

Rinse the aluminium oxide into a 15 ml centrifuge tube with small amounts of distilled water, centrifuge for about 2 minutes at 2500 r p m , drain off the water, and dry the inside of tube with filter paper

Add 5 ml of $N/5$ H_2SO_4 to the tube, mix thoroughly with a glass rod and by shaking, and centrifuge again for 2 minutes at 2500 r p m

Pipette 3 ml of the $N/5$ H_2SO_4 eluate into a 'Pyrex' tube containing 3 ml of 2% $NaHCO_3$, mix by shaking, then add 0 5 ml of 0 25% potassium ferricyanide, and mix again After 2 minutes add 1 ml of a mixture containing 9 parts of 20% NaOH and 1 part of 2% ascorbic acid (freshly made), mix, and centrifuge briefly

Pour the supernatant into a flat bottomed tube of non fluorescent glass and examine under ultraviolet light

Under these conditions preparations from normal urine show faint green fluorescence, whereas those from urine having an abnormally high catechol content show an intense bright green fluorescence For comparison a standard representing about 180 µg of catechols in 24 hours is prepared as follows to 100 ml of normal urine (containing about 4 µg of total catechols) add 50 µg of noradrenaline and make up to 200 ml with distilled water, extract catechols as described above and dilute the $N/5$ H_2SO_4 eluate with 2 parts of $N/5$ H_2SO_4 3 ml of this solution (which is stable for at least a month in the refrigerator) is used in developing the fluorescence as described above

Normal urine can readily be distinguished from urine containing 180 µg or more of catechols per 24 hour collection, and the approximate catechol content of the specimen to be analysed can be calculated by diluting the standard until the fluorescence equals that of the specimen to be analysed (total catechols in 24 hours = 180/D, where D = dilution necessary) , or, in a positive test, by diluting the specimen to be analysed to match the standard

If the volume of the urine is greater than 2 litres, 200 ml should be used and a suitable correction applied

Notes on Reagents

The aluminium oxide (chromatography grade) should be washed by shaking 200 g in a litre of hot *N*HCl, rinsing free from acid with several changes of distilled water, and drying The ascorbic acid should be kept in the ice compartment of the refrigerator, and the ferricyanide in a dark bottle The other reagents are stable

Preservation of Specimens

The catecholamines are stable in acid solution specimens not analysed immediately can be kept in the refrigerator for about a week without loss of activity if acidified to pH 5 or lower by addition of about 1 ml of concentrated H_2SO_4 A 24 hour specimen is advisable in so far as there is a diurnal variation in the excretion rate, the night excretion rate being significantly lower than the day excretion rate (Burn 1953, Von Euler et al 1955, Elmadjian et al 1956) , in severely paroxysmal cases, however, a single specimen taken following an attack may be more informative

Results

The method has been applied to the urine of 70 hypertensives suspected of having phæochromocytoma 69 of them were negative, giving approximate values of 15–132 µg (average 46 µg) of catechols per 24 hours The remaining patient, from whom a phæochromocytoma was later removed at operation, excreted about 1500 µg per 24 hours This value was in close agreement with those obtained subsequently on the same specimen by biological and colorimetric methods 10 days after operation this patient's excretion of catechols had decreased to about 75 µg per 24 hours

As a further check on the efficiency of this method of detecting increased urinary excretion of catecholamines, specimens of urine taken from athletes after strenuous physical exercise were tested These always showed the expected increase above the pre exercise values (Von Euler 1955), the approximate contents ranging from 75–210 µg per litre, with an average of 117 µg

I am indebted to Prof E J Conway, F R S , to the Rockefeller Institute for Medical Research and to the Medical Research Council of Ireland for facilities granted

FŒTAL BLOOD IN GENITAL HÆMORRHAGE DUE TO PLACENTA PRÆVIA AND ABRUPTIO PLACENTÆ

Y M Bromberg
M.D Paris
ASSOCIATE PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY,
HEBREW UNIVERSITY-HADASSAH MEDICAL SCHOOL, JERUSALEM

M. Salzberger
M D Jerusalem
RESIDENT, DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY,
ROTHSCHILD HADASSAH UNIVERSITY HOSPITAL

A Abrahamov
M.D Jerusalem
RESIDENT, DEPARTMENT OF PÆDIATRICS

It is generally agreed that, in cases of hæmorrhage due to placenta prævia or abruptio placentæ, maternal blood is lost from the ruptured uterine or decidual vessels, but the suggestion has been made (Macafee 1949, Busby and Neal 1951) that a proportion of the blood lost may come from the fœtal blood-vessels of the placenta, and that this loss may even suffice to cause anæmia of the newborn We report here the results of an investigation undertaken to establish whether genital bleeding due to placenta prævia or to abruptio placentæ carries fœtal blood as well as maternal blood Such an investigation is made easier by the fact that maternal blood does not contain more than 2% of fœtal hæmoglobin (alkali denaturation method, Singer et al 1951), whereas fœtal blood contains 50–100% (Walker and Turnbull 1955)

To determine the variations in amount of fœtal hæmoglobin in the blood of healthy women at term, clotted venous blood of 113 healthy women at term was examined by the method of Singer et al (1951) In 5 pregnant women with external bleeding due to placenta prævia, and in 2 women with abruptio placentæ, fœtal hæmoglobin was estimated in blood clots expelled vaginally before and during labour and, at the same time, in clotted maternal venous blood All the women were in the last month of pregnancy except 1 woman with abruptio placentæ in the seventh month

The clotted venous blood of 113 healthy pregnant women at term contained 0 3–2 3% (mean 1 4%, standard deviation ±0 53, and standard error ±0 081) of fœtal hæmoglobin In all 5 women with placenta prævia and 2 with abruptio placentæ the expelled blood contained more fœtal hæmoglobin than did the maternal venous blood, the differences between the two levels ranging being 0 8–2 3% (see table)

These results seem to show that the blood lost in the separation of the placenta in placenta prævia and in abruptio placentæ consists partly of fœtal blood, indicating that fœtal vessels have been damaged The amount of fœtal blood lost in this way was but small in the 7 women examined and was not large enough to cause anæmia of the newborn, it did not exceed 3–4 ml per 100 ml On the other hand, it has been suggested that, in rare cases of placenta prævia with marginal insertion of the cord, a large umbilical vessel may rupture, giving rise to considerable loss of fœtal blood (Wickster and Christian 1954)

FŒTAL BLOOD IN EXTERNAL GENITAL HÆMORRHAGE DUE TO PLACENTA PRÆVIA AND ABRUPTIO PLACENTÆ

Case no	Diagnosis	Fœtal Hb in expelled blood (%)	Fœtal Hb in maternal venous blood (%)	Difference (%)
1	Placenta prævia	4 1	1 8	2 3
2	,, ,,	4 3	2 2	2 1
3	,, ,,	3 0	1 1	1 9
4	,, ,,	3 5	2 3	1 2
5	,, ,,	2 1	1 3	0 8
6	Abruptio placentæ	3 5	1 8	1 7
7	,, ,,	3 8	2 2	1 6

Summary

In 5 cases of placenta prævia and 2 cases of abruptio placentæ the amount of fœtal hæmoglobin in blood-clots expelled vaginally before and during labour was estimated

In all 7 cases the expelled blood contained 0 8–2 3% more fœtal hæmoglobin than did the mother's venous blood

It therefore appears that, in the external genital bleeding of placenta prævia and abruptio placentæ, small amounts of fœtal blood are usually lost, though not enough to cause anæmia of the newborn

PREDNISOLONE SNUFF IN HAY-FEVER

A CONTROLLED TRIAL

M P Godfrey
M B Lond, M R C.P
MEDICAL REGISTRAR

Kate Maunsell
M.D Kiel
SENIOR MEDICAL OFFICER, ALLERGY CLINIC

R S Bruce Pearson
D M Oxfd, F.R C P
PHYSICIAN

KING'S COLLEGE HOSPITAL, LONDON

The efficacy of systemic cortisone, hydrocortisone, and corticotrophin in suppressing the symptoms of hay-fever is now well established (Toogood 1956) More recently there have been reports of good results following the use of oral prednisone and prednisolone in nasal allergy (Arbesman and Ehrenreich 1956, Brown and Seideman 1956, Feinberg and Feinberg 1956)

Since the systemic administration of all these drugs may produce undesirable side-effects, the advisability of their use in hay-fever has been questioned and Friedlander (1956) recommends that the treatment of hay fever with both the newer and the older steroids be restricted to severe cases which have not responded to other therapy However, the topical use of prednisolone in solution was effective and free from side effects in 30 patients with nasal allergy treated by Anderson and Ogden (1956) in a controlled trial Similarly Herxheimer and McAllen (1956) record the absence of side effects when using hydrocortisone snuff for the treatment of 24 patients with pollen hay-fever, 23 of these patients had 'excellent relief of symptoms, but the trial was uncontrolled

We present here the result of a small controlled trial in which patients with hay fever were treated by inhalation of either prednisolone snuff or an inert snuff containing lactose

Method

46 patients (23 males and 23 females), aged 12–54, entered the trial. All had a typical history of hay-fever, the duration of the disease varying from two to twenty years. 10 patients also had bronchial asthma.

A positive reaction to skin testing with mixed grass-pollens was obtained in each case. 18 patients had previously received one or more courses of pollen desensitisation, but none had received this treatment for at least a year.

The material for trial was supplied in two sets of capsules: one set contained 1 mg. of prednisolone with 144 mg. of lactose, and the other set 145 mg. of lactose only; the average size of the particles was 20 μ. The actual content of the capsules was not known until after the results had been assessed. The patients were arranged in pairs according to age and sex and were allotted to one of two groups at random.

A nasal insufflator was used to apply the snuff to each nostril in turn. The capsules were pierced at both ends with a household pin and inserted in the insufflator; pressure on the bulb produced a fine spray, and wastage was minimal. The patients were requested to use one capsule twice daily, dividing it as equally as possible between the nostrils. In no case was there initial difficulty due to blockage of the nose, but several patients using the control snuff complained that, after they had used the insufflator, their nostrils became obstructed. Anti-histamine tablets of chlorprophenpyridamine maleate ('Piriton') 4 mg. were provided, and the patients were instructed to use one or more of these tablets if the nasal insufflations did not control the hay-fever. Each patient was provided with a diary and asked to keep a daily record of (1) the presence or absence of hay-fever, and (2) the number of anti-histamine tablets used.

Diaries were kept from May 18 to July 7, 1956, and the trial was divided into three periods: (1) the fortnight beginning May 18 was used to assess the severity of symptoms in each group, no snuff being administered but anti-histamine tablets being taken as required for relief of symptoms; (2) from June 1 to June 30 the patients used the insufflator and took tablets of chlorprophenpyridamine maleate if their symptoms were not relieved; and (3) from July 1 to July 7 anti-histamine tablets alone were used.

RESULTS OF A CONTROLLED TRIAL OF PREDNISOLONE SNUFF IN HAY-FEVER COMPARED WITH RESULTS OBTAINED IN 18 PATIENTS TREATED BY POLLEN DESENSITISATION

Patients	—	Period in 1956					
		May 18–31		June 1–30		July 1–7	
		Hay-fever days	Anti-histamine tablets used	Hay-fever days	Anti-histamine tablets used	Hay-fever days	Anti-histamine tablets used

Results

Only 38 of the original 46 patients completed the trial. The 8 patients not included in the final assessment were rejected for the following reasons: 4 patients did not keep records; 2 devised their own treatment and did not adhere to the rules of the trial; 1 had persistent nasal blockage due to non-allergic disease in the nose; and 1 died in a motor accident.

There were 18 patients (9 male and 9 female) in group A (prednisolone) and 20 patients (9 male and 11 female) in group B (control). 7 patients in group A and 11 patients in group B had previously undergone pollen desensitisation.

During the initial observation from May 18 to May 31 the 18 patients in the prednisolone group (A) recorded 47 days on which hay-fever symptoms occurred, and required 56 anti-histamine tablets (means 2.6 hay-fever days and 3.1 tablets). In the control group (B) the 20 patients recorded 54 days' hay-fever (mean 2.7 days) and took 64 anti-histamine tablets (mean 3.2 tablets). The severity of the hay-fever in each group thus appears to be very similar.

From June 1 to June 30, during which time nasal therapy was given, the patients in group A (prednisolone) had 134 days of hay-fever (mean 7.4 days) and used 97 anti-histamine tablets (mean 5.4 tablets), whereas the patients in group B (control) had 285 days of hay-fever (mean 14.2 days) and used 460 anti-histamine tablets (mean 23.0 tablets).

Comparison of the two groups during this period of nasal therapy shows that the difference between the number of hay-fever days is not statistically significant ($P=0.05$), but that there is a significant advantage to the patients treated by prednisolone as regards the use of anti-histamine tablets ($P=0.01$). However, the number of hay-fever days merely indicates the presence or absence of symptoms and takes no account of their severity; it can therefore almost certainly be assumed that the quantity of anti-histamine tablets used provides a better indication of the efficacy of treatment.

6 of the patients in the control group (B) complained that use of the insufflator irritated the nose, and 3 thought that the snuff initiated attacks of hay-fever. Because of this 2 of the latter gave up using intranasal therapy a few days before the end of June. No side-effects, either local or general, were noted by the patients inhaling prednisolone snuff (group A).

During the first week after stopping insufflations (July 1–7) there was no significant difference between the groups. The patients who had been using prednisolone snuff (group A) had 22 days of hay-fever and used 39 anti-histamine tablets (means 1.2 days of hay-fever and 2.2 anti-histamine tablets), whereas the patients inhaling control snuff (group B) had 62 days of hay-fever and required 85 anti-histamine tablets (means 3.1 days and 4.2 tablets). If the hay-fever days recorded by each group are compared, $P=0.05$; similarly the difference between the number of anti-histamine tablets used is not statistically significant ($P=0.3$).

The patients' own assessment of the efficacy of treatment was recorded in each case. Of the 18 patients inhaling prednisolone snuff (group A) 16 thought that the treatment had been most effective, 1 considered it to have been fairly effective, and 1 considered it to have been of little value. The 20 patients of the control group (B) had different views: only 7 thought that the snuff had been effective, 2 considered it to have been fairly effective, but 11 said categorically that it was "no good."

The 10 patients with bronchial asthma (4 male and 6 female) were divided equally between each group. Of the 5 patients in group A (prednisolone) 2 recorded improvement in their asthma and had almost complete relief of hay-fever symptoms. In group B (control) 2 patients thought that their asthma had improved, but only 1 of this pair felt that the hay-fever had benefited from the snuff

While this trial was in progress a further 18 patients (8 male and 10 female, aged 13–50) with hay-fever were under observation in our clinics They had all been treated by pollen desensitisation and were provided with anti-histamine tablets (chlorprophenpyridamine maleate 4 mg) for relief of symptoms Although they do not form a control group, we recorded the results of their treatment for comparison with our other patients Desensitisation had continued until the end of May, 1956, and from May 18 to May 31 these 18 patients recorded 4 days of hay-fever (mean 0 22 days) and used only 6 anti histamine tablets (mean 0 33 tablets) From June 1 to June 30 they had 84 days of hay-fever and used 101 anti-histamine tablets (means 4 7 hay-fever days and 5 6 tablets) During the first week in July they had 21 days of hay-fever (mean 1 2 days) and used 35 anti-histamine tablets (mean 1 9 tablets) 14 of these patients commented that they had been almost completely free from hay-fever, and 4 had experienced fairly good relief of symptoms

The results are summarised in the accompanying table

Discussion

Although we deliberately administered a small dose of prednisolone to avoid the possibility of undesirable side-effects, our results suggest that the inhalation of prednisolone snuff is a promising method of controlling the symptoms of hay fever The 1956 hay-fever season was unusually mild, but this circumstance applied to both groups of patients, and pollen counts have shown that the peak of the season occurred during the period of nasal therapy from June 22 to June 28 (H A Hyde, personal communication)

Both the symptoms of rhinitis and the itching and congestion of the conjunctivæ were relieved by the inhalation of prednisolone A similar observation was made by Herxheimer and McAllen (1956) using hydrocortisone snuff for hay-fever Cotes et al (1956) have shown that the inhalation of 45 mg of hydrocortisone powder through the mouth produces an increased urinary excretion of 17-hydroxycorticosteroids, suggesting that hydrocortisone is absorbed systemically when inhaled from a powder spray It seems unlikely, in view of the small quantity of prednisolone used in our trial, that sufficient of the drug had been absorbed to exert a general effect, but this point requires further investigation

The 5 patients treated with prednisolone who had bronchial asthma in addition to hay-fever are so few that it is impossible to draw any definite conclusion about the efficacy of prednisolone snuff in bronchial asthma

The relief of symptoms in the group treated by inhalation of prednisolone compares satisfactorily with the experience of the patients who had been desensitised to pollen The latter therapy, though usually effective, is somewhat undesirable because of its potential danger and the necessity of weekly injections for three months before the start of the hay-fever season We therefore consider that our results warrant a more extensive trial of prednisolone snuff, which may provide a simple, safe, and effective remedy for hay fever

Summary

The effect of the inhalation of prednisolone snuff was compared with that of placebo snuff in patients with hay fever

38 patients were studied 18 in the prednisolone group and 20 in the control group Treatment was given from June 1 to June 30 1956

The results suggest that the daily inhalation of 2 mg of prednisolone snuff is of considerable value in the control of symptoms due to hay fever

No side effects were observed after the inhalation of prednisolone, and this treatment is considered to be worthy of more extensive clinical trial

One of us (K M) has done part of this work with the assistance of a grant from the Geoffrey Duveen Trust

We are very grateful to Messrs Pfizer Ltd for providing the two sets of capsules and the nasal insufflators, and to Dr M J H. Smith for help with the statistics

BILATERAL BRONCHIAL FOREIGN BODIES

T Semple
M D Glasg , F R C P.E , M R C P
CONSULTANT PHYSICIAN, VICTORIA INFIRMARY, GLASGOW

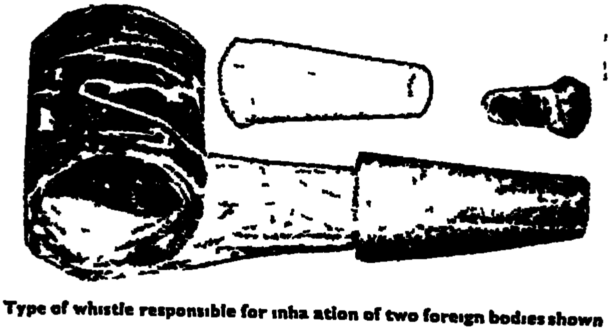
W J O Page
F R C S.E , D L O
CONSULTANT E N T SURGEON, CUMBERLAND INFIRMARY, CARLISLE

The rarity of such an occurrence, with the unusual and misleading bronchoscopic appearance produced, prompts us to report this case of simultaneous inhalation into the right and left lower lobe bronchi respectively of a metallic radio opaque and a plastic radiotranslucent foreign body The latter remained in situ unrecognised for ten months despite several bronchoscopic inspections

Case-report

A farmer, aged 35, was dancing at a Christmas Eve party when he inhaled part of a " blow out " whistle (see figure) Forceful exhalation produced a slight whistling sound from the right side of his chest On arrival at hospital about two hours later, radiography revealed the presence of a metallic reed in the lower lobe of his right lung At bronchoscopy the reed was easily found and removed without difficulty The left bronchus was not inspected The patient's statement that he had inhaled a plastic whistle was discounted because of his somewhat convivial state on admission and the absence of any abnormal clinical or radiological signs at the time of discharge from hospital three days later

About two months later he developed a wheeze and later a cough with occasional bloodstained sputum and slight left sided chest pain Further radiography during the ensuing months did not reveal any abnormality Nine months after the incident a chest physician reported excellent general health, a recurrent dry cough, and rhonchi on auscultation, chiefly on the left side, with good air entry to the left lung *The result of bronchoscopy by the chest physician at this* time was reported as follows "Marked fœtor In the left stem bronchus, below the left upper lobe orifice, there is gangrene The whole bronchus from this level down appears to be involved It is avascular and completely covered by white slough There is a sharp line of demarcation between this and the proximal part of the main bronchus, which is entirely healthy Basal orifices can just be seen, and there is no foreign body "



Type of whistle responsible for inhalation of two foreign bodies shown

Accordingly the patient was transferred to a chest surgery unit, where he was described as being in excellent general condition and apyrexial, with a wheeze present over both lungs but loudest at the left base Nothing abnormal was found on radiography Bronchoscopy was repeated, and a similar report was given of the appearances in the left lower lobe bronchus Coliform organisms were grown from the bronchus, and the patient was given a course of chloramphenicol Once more he was submitted to bronchoscopy (by a fourth bronchoscopist) and on this occasion palpation with forceps revealed the "gangrenous slough" to be a tubular piece of yellow plastic, the original mouth-piece of the whistle This was removed with some difficulty It had fitted the left lower lobe bronchus snugly between the apical and distal segmental bronchial orifices, thus producing no obstruction and allowing a clear view of all segmental orifices The patient's symptoms were relieved immediately, and the wheeze disappeared at once

Comment

The only previous report that we have been able to discover of bilateral bronchial foreign bodies is that of Orton (1924), who removed half a peanut from the right stem bronchus of a child and the other half two days later from the left side Here also the left bronchial tree was not inspected at the original bronchoscopy Orton states that Chevalier Jackson at that time had seen three cases in which peanuts acted as bilateral bronchial foreign bodies

Examining our patient's X-ray films in retrospect we could just make out the faint outline of the plastic tube It was very faintly radio opaque, whereas the metal reed was, of course, distinctly so It was unsuspected because of the rarity of simultaneous inhalation of dual foreign bodies and the very faint radio-opacity, it was undiscovered at the first examination because the examination was incomplete, the left bronchus not being inspected The appearances at two subsequent bronchoscopic examinations, some months after the original one, did not arouse suspicion of this second foreign body because of apparent disease within the left bronchus, the preservation of a clear lumen, and possibly because the bronchoscopists were less familiar with the details of the original incident and examination

The immediate disappearance of the generalised bronchospasm on the removal of the offending foreign body was very striking It brought to mind the reflex bronchospasm not infrequently found in patients with localised disease in the bronchus or in the lung In such patients, perhaps also having chronic tuberculosis, bullous emphysema, or bronchial adenoma, operation may be long delayed because of associated "generalised bronchitis," only to find that the rhonchi, which have failed to respond even partly to medical measures, have disappeared immediately after resection

It is worth remembering that generalised, as distinct from local, bronchospasm may have a reflex ætiology from a focal source of irritation

Summary

A man inhaled the proximal end of a toy whistle

The metallic radio opaque reed was removed from the right lower-lobe bronchus about four hours after the incident, but the plastic mouth-piece remained in the left lower-lobe bronchus for ten months and was recognised and removed at a fourth bronchoscopy

No localising radiological signs were produced by this tubular plastic foreign body, but reflex bronchospasm was relieved immediately by its removal

We are grateful to Mr Bruce Dick, of the Hairmyres Hospital thoracic unit, for his encouragement and permission to publish

Preliminary Communication

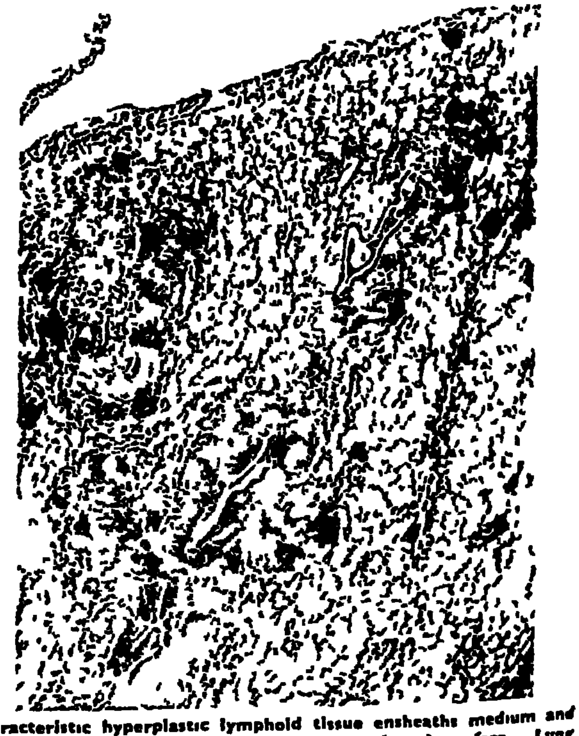
NON-TUBERCULOUS JUVENILE BRONCHIECTASIS A VIRUS DISEASE?

NON-TUBERCULOUS bronchiectasis in the child is usually ascribed to some ill-defined episode of pyogenic bronchitis, perhaps complicating a specific fever We suggest that, in a substantial number of such cases, the lesion is due to chronic infection of the bronchi with the adenovirus (A P C virus), and that some of the characteristics of the lesion are due to the persistent presence of virus

This suggestion arose from the demonstration to us by Dr W F H Jarrett, of the veterinary pathology department of Glasgow University, of the lesions of the common respiratory disease of cattle which he has described[1] under the name of "cuffing pneumonia" and has suggested might well be of virus ætiology Since this work was begun, the description by Innes et al[2] of similar lung changes in the rat, which they ascribe to infection by the Nelson rat lung pneumonia virus, adds further support

Jarrett[1] has shown that the cattle disease begins in the calf in an acute form with mild peribronchial lymphocytic infiltration, passes through a chronic stage in which lymphoid hyperplasia is the main feature, and ultimately develops into bronchiectasis with fibrosis

From early 1956 our morphological investigation of lobectomy specimens from patients with bronchiectasis indicated strongly the presence of a similar process in human lungs In brief, the dominant feature present in about three quarters of the cases was lymphoid hyperplasia affecting the hilar nodes and irregularly narrowing the lumen throughout the whole length of the bronchial ramifications in the affected segments or lobes (see figure) In 1948 Cruickshank[3] investigated bronchiectasis in rats and suggested that lymphoid hyperplasia might



Characteristic hyperplastic lymphoid tissue ensheaths medium and small bronchi and extends almost to pleural surface Lung parenchyma is not severely diseased (Hæmatoxylin and eosin ×10) play some part in the pathogenesis of bronchiectasis in children A comparison of healthy lungs and of lungs showing other types of chronic disease, with the bronchiectasis material, has confirmed the impression that lymphoid hyperplasia is the important feature in bronchiectasis

INVESTIGATION AND RESULTS

These considerations led us to investigate the possibility of demonstrating a virus in such patients In 18 cases so far investigated serological tests were made before and after operation, and the resected specimen was used for bacteriological, virological, and histological investigation At first complement-fixation tests, as described by Grist,[4] were made with antigens from several possible viruses influenza viruses A, B, and C, newborn pneumonitis virus (type Sendai), and the adenovirus group After testing the first 8 sera, however, we saw that positive results were being obtained only with the adenovirus-group antigen, our attention was therefore concentrated on this group

8 of our cases showed a titre of 1/16 or over, 3 one of 1/8, and 7 one of less than 1/2 Our previous experience with complement-fixation tests in 600 cases of respiratory disease suggests that titres of 1/16 or more, in single or repeated specimens, indicate continuing adenovirus infection, whereas titres of 1/8 are doubtful and those below 1/8 are negative

In 1 case with positive serum more conclusive evidence of the rôle of the adenovirus in bronchiectasis was obtained with the isolation from the resected lung tissue and hilar lymph-nodes of an agent which produced the cytopathogenic changes in tissue culture and the complement fixation reaction characteristic of an adenovirus

DISCUSSION

Many of the pathological features of these cases can be attributed to the secondary effects of lymphoid hyperplasia, which is apparently the characteristic lesion causing irregular bronchial stenosis That the adenoviruses are responsible for this, at least in many cases, is less surprising when we consider their rôle in connection with lymphoid hyperplasia at other sites (tonsils and adenoids,[5] conjunctiva,[6] and mesenteric lymph-nodes [7])

In bronchiectasis pyogenic infection is important, of course, and it is not our purpose to minimise the rôle of *Hæmophilus influenzæ* [8 9], but we suggest that, as in influenza, the primary pathogen is a virus, and that pyogenic bacteria are secondary invaders

We are investigating the relation of the adenovirus group not only to the relatively well recognised acute respiratory diseases but also to chronic lung disease, which is considered to be an intermediate stage in the development of bronchiectasis, and already we have serological evidence of its association with some cases of "sinobronchitis"

SUMMARY

Lymphoid hyperplasia is an important element in most cases of juvenile bronchiectasis

Resemblance to animal diseases which are almost certainly of virus origin prompted search for a virus in such cases

Of 18 cases so far investigated serological evidence of adenovirus infection has been obtained in 11 and an adenovirus has been isolated in 1 case

We acknowledge with pleasure our indebtedness to the following physicians and surgeons whose willing coöperation provided us with the clinical cases Prof S G Graham and Dr J H Hutchison, Messrs R S Barclay, K. Fraser, T M Welch, R A McCluskie, and N McSwan, to Prof D F Cappell and Dr G B S Roberts, who made available histological material from their departments to Miss Helena S Adamson, B SC, for making the bacteriological tests to C McLean, F I M L T, for assistance with the serological tests and to the house surgeons at the thoracic units concerned for their help in obtaining specimens

P S M also gratefully acknowledges the constructive criticism given him by Dr W F H Jarrett of the veterinary pathology department of Glasgow University and the encouragement offered and facilities made available by Dr A M MacDonald

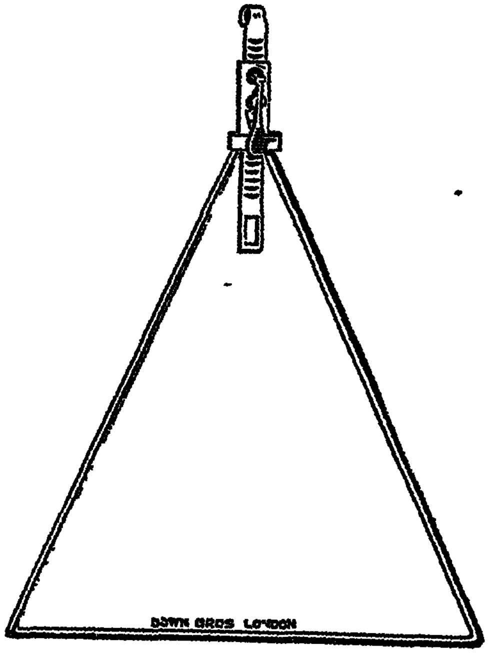
New Inventions

INSTRUMENT FOR RATCHET SUSPENSION OF THE BOYLE-DAVIS GAG FOR TONSILLECTOMY

THE accompanying diagram illustrates a suspension instrument designed for this purpose It is a triangle, constructed of a steel rod, which carries a sliding bar with ratchet at the apex of the triangle, the bar has a large slot at the bottom to accommodate the hook of the Boyle-Davis gag



The triangle is slipped over the patient's head, the cross-bar base of the triangle prevents skidding and damage to the rubber cushion of the operating-table.

The ratchet mechanism is similar to that on the Boyle-Davis gag and allows easy, quick and accurate adjustment and release of the gag This is of advantage if it is found necessary to reposition the gag during operation, and it also enables the surgeon to get the necessary position of the head without raising it from the operating-table The degree of adjustment on the ratchet enables the suspension to be used for adults and children

This instrument incorporates the principle of suspension by the 'Draffin Bipods'

I wish to thank Mr Maurice Down, of Down Brothers & Mayer and Phelps Ltd, for his help in constructing the instrument

Reviews of Books

Taylor's Principles and Practice of Medical Jurisprudence

11th ed Vol I Editors SIR SYDNEY SMITH, C B E, F R C I E, F R S F, emeritus professor of forensic medicine, University of Edinburgh, KEITH SIMPSON, M D, reader in forensic medicine, University of London London J & A Churchill 1956 Pp 626 70s

"Taylor" first appeared in 1865, but the 11th edition bears few marks of antiquity Dr Keith Simpson is now associated with Sir Sydney Smith, an editor since 1928, so this famous work has now, in part, returned to Guy's

From 1865 until 1905 it stayed in the Borough, for Stephenson took over from Taylor In that year, however, it journeyed across London Bridge to Whitechapel, where F J Smith of the London Hospital became its new author His chief alteration was to introduce "small print" for quoted cases and to discard not only the illustration of the "Waterloo Bridge body" but also that of Dr Parkman, who was, however, restored to favour in a later edition In 1928 it moved again, this time north of the Border to Edinburgh into the capable and experienced hands of Sydney Smith who introduced new material but retained the small print which still remains Now he is joint editor with Keith Simpson, who has obtained valuable assistance from Gerald Howard, Q C, M P

As Sir Sydney says in his preface, Dr Simpson's influence can be observed in most sections, for not only has he included many of his well-known cases but he brings his characteristic style The text has been thoroughly revised, and several sections have been largely rewritten Nearly three hundred new cases and some forty new illustrations have been introduced The legal aspect has been revised by Mr Gerald Howard, a section on psychiatry and the law contributed by Dr David Stafford-Clark, and the chemical aspect revised by Mr L C Nickolls, director of the Metropolitan Police laboratory at New Scotland Yard

In forensic medicine, as in so many other branches of medicine, the days are past when a single expert can pronounce authoritatively on all questions As the senior editor remarks

"The assistance of the chemist, the physicist, the biologist and of experts in other branches of science has given greater precision in our work with a corresponding increase in the value of evidence Over all, however, there must be someone who is able to advise on the procedure to be adopted, the particular scientist whose help should be sought, and who takes a final responsibility of advising the Crown Thus there would appear to be no lessening in the need for a general work such as this " The editors of such a work must try to be clear without being dogmatic, for counsel may cite them as the ultimate authority, and if they have expressed their views with insufficient reserve the court may give different opinions less than their due weight

This leading reference book is indispensable to medical jurists The second volume in the new edition is expected to appear in a few months

Cytologic Technics for Office and Clinic

H E NIEBURGS, M D director of the Cytology Laboratory, Bethel Hospital New York, London and New York Grune & Stratton 1956 Pp 233 $7 75 -

MAKING no pretence to teach the art of cytological diagnosis, this eminently practical manual ranges over all parts of the body to which the technique has been applied recently "Recently" is an important qualification "cytology" has a curiously limited meaning in this context for instance, in the urine it is applicable to the diagnosis of tumours by examination of the sediment, but not to the more old-fashioned method of diagnosing nephritis The main diagnostic possibilities are considered at each site and the method of obtaining suitable specimens is considered in detail The section on laboratory organisation, dealing as it does with the methods necessary in handling material in bulk, may well prove to be the most valuable part of the book

Tratamiento de la Meningitis Tuberculosa y de la Tuberculosis Pulmonar Aguda

DR JUAN TORRES GOST, Sanidad Nacional de la Lucha Antituberculosa oficial Madrid España Calpe, S A 1955 Pp 122

THIS monograph summarises Dr Torres Gost's experience in the treatment of meningeal and pulmonary tuberculosis. He pleads for the association of isoniazid and streptomycin in the management of meningeal tuberculosis and records an overall mortality of 6 7% in a series of 278 cases This is a very high proportion of successes, which cannot be matched in this country Since other Spanish workers have achieved similar or even better results—Ramos and Soriano for example—using isoniazid alone, it may be that tuberculous meningitis is less severe in Spain than it is in this country The treatment is set out in detail, and some guidance about the handling of complications adds interest The second part of the book is concerned with the role of antibiotics in pulmonary tuberculosis

Stress and Strain in Bones

Their Relation to Fractures and Osteogenesis F GAYNOR EVANS, PH D, associate professor of anatomy, Wayne State University College of Medicine, Detroit, Michigan Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 245. 50s

MOST of the recent experimental work upon the effects of mechanical forces on the skeleton has here been collected and examined The book is introduced by an explanation of the techniques which can be used, and it contains a critical examination of the applications and importance of the photo-elastic, stress-coat, and strain gauge techniques A consideration of stress and strain in long bones occupies most of the space, though there are useful sections on the skull and on the effect of stress upon development and bone healing and growth In certain regions the relationship between bone architecture, deforming forces, and fractures is considered, and for the femoral neck the analysis is made in great detail Dr Evans's main interest, however, has been in experimental work, and many of the illustrations are derived from his own investigations The text is remarkable for a most critical and stimulating reappraisal of the classical contributions to this subject, and the extensive bibliography will help to make this a ready source of reference

---

The Essentials of Modern Surgery (5th ed Edinburgh and London E & S Livingstone 1957 Pp 1276 75s)—This work is reputed to be amongst the most popular text books of surgery for medical students It was an immediate success when it first appeared eighteen years ago, and it continues so as it matures with each successive edition under the editorship of Mr R M Handfield Jones and Sir Arthur Porritt Inevitably the cost has increased, but it is still excellent value

The Diseases of Occupation (2nd ed *London* The English Universities Press 1957 Pp 1100 £3 5s)—The appearance of another edition of Dr Donald Hunter's book so soon after the first indicates its usefulness and "box office" appeal A few additions have been made to the chapters on the historical aspects, and there are 11 new illustration The descriptions of poisoning by vanadium manganese and cadmium have been brought up to date, and substantial new sections on thallium poisoning, iron and steel foundries and the risks of work in sewers have been added The new sections are as instructive and entertaining as the old one and the whole book is uncommonly readable A new comment on the dangers of sandblasting says "of course the men themselves are aware of the hazard" thus in 1934 in a works in Coventry they put up a notice "Join the Navy and see the world Become a sandblaster and see the next" The first edition was criticised because no attempt was made to deal with the "epidemiology" of industrial diseases Fortunately Dr Hunter has resisted the temptation to besprinkle his pages with curves, graphs, and correlation coefficients on which the general reader usually looks with a glassy eye He has remained faithful to his purpose—"to review on a broad basis and with emphasis on its clinical aspects the problem of disease in relation to occupation" The book is well on its way to becoming a classic

THE LANCET

LONDON SATURDAY, APRIL 13, 1957

Discussion First

ALMOST every doctor in the country must now feel that the Government have been treating the profession neither justly nor courteously In a group of experienced laymen the same feeling was evoked last week by Lord MORAN's moderate statement of the profession's case[1], and to onlookers it seemed that, on a division, the House of Lords would have registered its evident opinion that on the point at issue—the terms of reference of the Royal Commission—the Government should think again Unfortunately, in their present mood, that is exactly what the Government are not prepared to do Having announced their programme, they intend no concession that might be put down to the British Medical Association's threat of direct action Were they otherwise untroubled and secure, they might attach less importance to so small a matter of prestige, but in face of many perils their need of confidence makes them chary of reversing even small decisions In this dispute some of their decisions, taken without consultation, have been rightly described as dictation, and this way of dealing with complex issues is wholly unsuited to the National Health Service On the other hand, the B M A 's objection to dictation is invalid so long as it is itself proposing, by a form of strike, to dictate terms of settlement to the Government In using these methods both sides are at fault and in everybody's ultimate interest the need is to get away quickly from dictation and counter-dictation and return to the plane of civilised discussion

The profession is not responsible for the Government's actions, but it is entirely responsible for its own, and this responsibility will not be properly discharged unless it ensures that these actions are beyond reproach In discussions up and down the country the plan for "phased withdrawal" from the National Health Service has had an uneasy reception —partly because it is thought likely to be ineffective but partly because this means of exerting pressure on the Government is seen to be wrong The growing demand for complete rather than partial withdrawal is not wholly due to growing belligerence or to the natural preference for unanimous action it also springs from the knowledge that deliberate resignation from the service is professionally defensible, whereas any kind of temporary strike is not Fortunately, though the threat of action has been freely used, no decision on its nature can be taken by the B M A until the representative body meets on May 1, and perhaps the representatives will then come to the correct conclusion that withdrawal, if undertaken at all, must be final If that were their opinion, the next step must be for their leaders to produce a scheme whereby, with sufficient notice, the bulk of general practice could be removed from the National Health Service For our part we should profoundly regret such an outcome of the present disagreements, but this kind of withdrawal is feasible, and it would be justified if, after full consideration, a majority of practitioners felt that the service denied them satisfaction in their calling At the same time, such a decision is certainly not one to be made without examining the implications, or without devising alternative arrangements for practice which might protect the public from suffering by the change Since apparently no such plan has yet been worked out in detail, we may reasonably hope that, before practitioners are finally asked to decide on it, they will at least have heard what the Royal Commission recommends and what the Government propose to do

What, in the meantime, should be the profession's attitude towards the Royal Commission ? Its appointment without consultation was something not easily forgiven, the suitability of such a body for its task is questionable, and, by refusing to give evidence before it, doctors could make a dignified protest against the Government s arbitrary handling of their affairs The temptation to such a protest is great, but in so far as its origin is emotional it should be resisted—if only because a boycott would inconvenience the Government very little, and instead of arousing general sympathy might impress the public unfavourably Far more important than indignation as a reason for refusing to help the commission is the serious doubt whether its terms of reference will let it give proper consideration to the conditions on which doctors entered the service, and unless it can do this it will be wasting its time so far as the profession is concerned Lord JOWITT, as a lawyer, and others in the Lords' debate, clearly thought it rash to proceed unless the Government will remove this uncertainty by altering the commission's remit On the other hand the Government spokesman, Lord HOME, said

> " there is no reason to think that they [the Royal Commission] will not put a realistic interpretation upon their terms of reference, nor any doubt that they will listen to any evidence put before them which is relevant " They can " take into account all the circumstances that are relevant, and one of the factors which is clearly relevant is consideration of the Spens reports Clearly, the Royal Commission will take into account rewards for skill in other comparable professions and, equally, the special conditions of a doctor's life—the long and irregular hours, the load of responsibility, great in human terms and the financial factors, which affect recruiting to a profession which is of such vital importance to the community "

Doubtless it is true, as Lord MORAN pointed out, that a Royal Commission is closely restricted by its terms of reference, and that no Minister—indeed nobody except the chairman of the commission—can decide what is within its ambit But to boycott the commission at this stage because doctors have no guarantee that the Government spokesman is not misinformed would be to carry the legalistic approach altogether too far (Some of us think that legal advisers have already had too much influence in the negotiations) If the commission should in fact find itself legally debarred from taking into account " all the circumstances that are relevant," including the Spens reports, the Government would then be bound in honour to add another paragraph to its terms of reference—a recent precedent (Lord MORAN said) being provided by the Royal Commission on Taxation, whose remit was modified half-way through its proceedings Though the Government may feel unable to do this now at the demand of the profession, they might do it quite easily later at the request of the commission. Similarly if, as we expect, Sir **Harry Pilkington** comes to feel the need of one or two colleagues with a good background knowledge of the National Health Service or the profession, persons of this kind (guaranteed non-medical, of course) might presently be discovered and added to the membership. Possibly they could not actually be industrialists, but the balance of the commission need not be gravely disturbed.

---

[1] See p 793

The State, remarked Lord **Home**, has "no inherent virtues as an employer." This "is the first time it has had to work out a relationship with one of the great skilled professions, and inevitably, I suggest, it must take time . . . before a satisfactory code of relationship and conditions of service can be finally established." We shall all agree with him that it has taken time. "It has been heartbreaking," as Lord **Moran** put it, "to see all this bungling and mishandling of the human element." But at the present juncture it would be foolish as well as unfair to treat the Royal Commission as though it too bears responsibility for past failures. Unless or until it proves itself otherwise, the commission should be regarded as a body of reasonable people anxious to do all it can to form a reasonable opinion on the evidence before it; and those who, in protest against the Government, would refuse the commission cooperation should ask themselves whether they would really like it to reach its conclusions without ever hearing the case for the profession put by the profession. Though neither side will be bound by its recommendations, these cannot fail to affect both public opinion and Government policy; and the chance of their being constructive and practicable will be much smaller if the commission has guidance in only one direction. Finally, if it had no other advantage, cooperation with the commission would be desirable because it will oblige all parties to state their case in reasonable and persuasive terms. The horrifying alternative is a period of unrelieved hostility in which the normal flora of discussion gives place to pathogenic propaganda.

Rectal Biopsy

The use of biopsy to confirm a clinical diagnosis of rectal cancer was first recommended by **Gabriel** in 1931,[1] and this was soon adopted at St Mark's Hospital as a routine aid in the diagnosis of neoplasms and obscure granulomatous lesions.[2] More recently rectal biopsy has been advocated for the control of cortisone treatment in ulcerative colitis;[3] but it was found that, in general, the mucosal changes appear much the same at the end of treatment as at the beginning, even when symptomatic relief is complete and sigmoidoscopic appearances are greatly improved.[4] In some cases the surface epithelium appears more gravely disturbed during treatment than before. **Lumb** and **Protheroe**[5] found that in ulcerative colitis the correlation between histological appearances and clinical and sigmoidoscopic findings was close, but that in quiescent cases microscopy might sometimes show the characteristic histological changes of ulcerative colitis even when the mucosa seemed normal by sigmoidoscopy. In the quiescent phase the change is always towards diminution in the numbers of crypts and a generalised thinning after destruction during the ulcerative phase; the regular arrangement of crypts which is so characteristic of the healthy mucosa is generally lost even when repair has taken place; but, although biopsy may thus reveal the existence or persistence of ulcerative colitis, it is not a reliable method of deciding the severity of the disease or of foretelling its future course.

On p. 763, Sir **Philip Manson-Bahr** and Mr **Muggleton** discuss rectal biopsy in the diagnosis of amœbic dysentery and other disorders. They obtain biopsy material by scraping the suspected area of the rectal mucosa with a long-handled Volkmann spoon, crushing the small fragment under a cover glass, and examining it immediately with a low-power objective of the microscope. (The more usual method of obtaining material is by means of a punch or special forceps; the fragment is then fixed, dehydrated, sectioned, and stained by conventional histological techniques.) Of 30 cases of amœbic dysentery, amœbæ or cysts were found in 23 by stool examination and in 15 by biopsy. But the active vegetative form of *Entamœba histolytica* was found in 7 cases by the proctoscopy scrape preparations when all the routine stool tests had been negative; 3 of these 7 had no previous history of amœbic infection. In the more acute phases of the disease diagnosis by examination of material obtained through the sigmoidoscope has been in common use for many years, and has been repeatedly recommended by Sir **Philip Manson-Bahr**.

Rectal biopsy for the diagnosis of schistosomiasis was first suggested in 1942 by **Ottolina** and **Atencio**,[6] who had noticed in necropsy material that the greatest number of *Schistosoma mansoni* ova was to be found in the upper half of the rectal ampulla. Since then this method has often been used when examination of the fæces has proved negative. The comparative value of stool examination and rectal biopsy has been investigated by **Spingarn** et al.,[7] who examined 187 patients with *S. mansoni* infections and found ova in 93% by biopsy and in 83% by stool examination. They attributed the superiority of biopsy both to the concentration of ova in the upper half of the rectal ampulla and to the fact that few ova escape from the colonic wall as the infection becomes chronic. In the acute stage, after deposition within venules by the adult female worms, the ova traverse the tissue spaces rapidly and many appear in the stool; but in the chronic stage a host-cell reaction impedes their progress and smaller numbers are evacuated. The ova which do not escape soon after deposition may die and become calcified. Necrotic ova are still recognisable by microscopic examination of biopsy fragments.

Before recommending the more general use of rectal biopsy we must be sure that it is indeed relatively harmless. **Truelove** et al.[3] found that small erosions caused by taking biopsy material healed without scarring within a few days. They decided that the risk of serious injury by their method was slight, but admitted that any break in the rectal or colonic mucosa might lead to ischiorectal abscess or perforation of the bowel At some hospitals, including St Mark's, rectal biopsy has been adopted, almost as a routine, to confirm a diagnosis of carcinoma and as an aid to the diagnosis of obscure lesions, and it has been found that material can be safely taken in the outpatient department without anæsthesia and without any preliminary preparation, provided that suitable instruments are used and that the operator is experienced in sigmoidoscopic technique

Annotations

ORAL PREPARATIONS FOR TREATMENT OF PERNICIOUS ANÆMIA

If our present ideas about the ætiology of pernicious anæmia are correct, it should be possible to treat patients successfully by giving them orally a preparation of intrinsic factor (hæmopoietin) together with a relatively small dose—say 30–45 µg —of vitamin B_{12} Preparations of vitamin B_{12} and intrinsic factor made from hog's pylorus or hog's duodenum have been marketed, but the results have been curiously disappointing Blackburn et al [1] used a preparation dispensed in tablets each of which contained 6 µg of vitamin B_{12} and 30 mg of an intrinsic factor concentrate They gave five tablets a day to 5 patients with pernicious anæmia in relapse, 4 responded reasonably, if slowly, but the 5th did not respond at all, though 30 µg of vitamin B_{12} given intramuscularly each day produced a satisfactory rise in red cells and hæmoglobin Maintenance with one tablet a day showed that after a time, usually about six months, the blood levels began to fall, and in 1 patient signs of neurological involvement developed Blackburn et al concluded that either they had not given big enough doses or the effectiveness of the intrinsic factor concentrate was falling off Dr Schwartz, Dr Lous, and Professor Meulengracht in Copenhagen have met with similar disappointing results, and on p 751 of this issue report investigations that suggest another explanation

They used the test devised by R F Schilling that utilises the urinary excretion of an orally administered test dose of vitamin B_{12} labelled with radioactive cobalt In a healthy person vitamin B_{12} is absorbed in the intestine and excreted in the urine, and the amount excreted gives a measure of the degree of intestinal absorption The patient with untreated pernicious anæmia absorbs hardly any vitamin B_{12}, so very little appears in the urine, but if an effective source of intrinsic factor is given with the vitamin B_{12}, absorption takes place and is reflected in the urinary excretion In health 10–38% of the orally administered vitamin B_{12} is excreted in the urine, whereas in untreated pernicious anæmia the figure is 0–8% The Copenhagen workers gave a combination of labelled vitamin B_{12} and intrinsic factor made from hog's pyloric mucosa to three groups of patients those with untreated pernicious anæmia, those whose pernicious anæmia had been treated with intramuscular vitamin B_{12} or liver extract, and those whose anæmia had been treated orally with a combination of vitamin B_{12} and hog's pyloric mucosa for periods ranging from six months to four years They found, as have others,[2] that up to a certain maximum the absorption of vitamin B_{12} increases with the amount of intrinsic factor given, with their preparation, the most effective dose was about 100 mg daily When this dose of intrinsic factor together with labelled vitamin B_{12} was given to patients with untreated pernicious anæmia the greatest proportion of the test dose excreted in the urine was 20–25%, patients whose pernicious anæmia had been treated with intramuscular vitamin B_{12} or liver gave a similar figure; but most of the patients treated orally showed remarkably low urinary excretion figures, varying from nil to 16% When a *human* source of intrinsic factor, in the form of 100 ml of normal gastric juice, was given with the labelled vitamin B_{12}, this was absorbed as fully by the third group of patients as by the other two groups

Dr Schwartz and his colleagues consider that long treatment with heterologous intrinsic factor must be connected with the long-term failure of these orally administered combinations of vitamin B_{12} and intrinsic factor, but they cannot suggest an explanation Wijmenga,[3] addressing the 1956 Hamburg conference on vitamin B_{12} and intrinsic factor, pointed out that there was evidence that intrinsic factor might be specific for each species, though it is known that activity is not limited to one species—for hog's intrinsic factor is active in man But he also cited some investigations suggesting that intrinsic factor concentrates prepared from one species might contain substances that inhibit the absorption of vitamin B_{12} in other species Williams et al [4] actually prepared intrinsic factor fractions some of which augmented and some inhibited the absorption of vitamin B_{12}, judged by the Schilling test Nevertheless physicians have had entirely satisfactory results from the treatment of pernicious anæmia over periods of many years by administration of relatively crude preparations of hog's stomach Thus Wilkinson [5] reported that of 441 patients treated for six or more years with preparations of desiccated hog's stomach, only 15 relapsed, these relapses occurred only because the patients neglected treatment and they responded promptly when given proper treatment again The cause of the failure of the present intrinsic factor concentrates may well lie in the method of preparation, and this needs to be fully explored as well as possible resistance, or inhibitors, arising because of the heterologous source of intrinsic factor Meanwhile practitioners can take the hint and avoid these relatively very expensive oral preparations for the treatment of pernicious anæmia

TRANQUILLISERS AND SOCIETY

Concern at the increasing abuse of tranquillisers has been expressed by the W H O Committee on Addiction-producing Drugs [6] In the U S A in the first ten months of last year some 30,000 million tablets of one particular tranquillising drug are said to have been sold to the public This figure is cited by Dickel and Dixon,[7] who report 328 instances of "physical dangers" arising from the treatment with tranquillisers of 8200 patients in the past eight years

The main thesis of Dickel and Dixon is that the dangers of abuse are altogether more subtle and pervasive than the occasional development of a skin rash or a blood dyscrasia [8] They consider that such abuse has caused emotional, moral, and philosophical dangers to the patient, dangers to medicine and the physician, and dangers to the whole structure of society In their experience, undesired emotional responses to tranquillising drugs occurred in 827 emotionally ill patients, whose condition was aggravated and distorted by these drugs Equally disturbing were 1700 instances in which serious problems were created in the minds of essentially normal people by the misuse of tranquillisers What very often

SOCIAL PATTERNS OF ANTIBODY TO POLIOVIRUS

E MAURICE BACKETT
M B , B Sc Lond , M R C P , D P H
SENIOR LECTURER IN SOCIAL MEDICINE AND PUBLIC HEALTH, GUY'S HOSPITAL MEDICAL SCHOOL AND THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE *

From the Department of Social and Preventive Medicine, The Queens University of Belfast

THE recent introduction of poliomyelitis vaccines is likely to upset for all time the natural poliovirus antibody patterns in Western communities If anything can be learnt from the distribution of antibody in these communities, it must be learnt now The social factors which are concerned with the spread of polioviruses through a population are not fully understood, and most of our knowledge comes from comparing the antibody patterns and vital statistics of countries with high and low standards of living In general, poliovirus infection has been found to be more common in the countries with a low standard of living, but paralytic poliomyelitis and poliomyelitis epidemics are more common in the countries with a high standard of living (World Health Organisation 1954, Paul 1955)

In this paper, antibody patterns have been related to a variety of social characteristics which reflect the standard of living of the children within a single community This has been done in an attempt to define in greater detail which social factors are associated with the spread of infection between groups in this community, and to see if they are the same as those which seem to operate between countries

As part of the preparation necessary for a field trial of poliomyelitis vaccines, the antibody patterns of a group of children in Northern Ireland were studied by Dane, Dick, Connolly, Briggs, and McLeod in 1956 295 of these were available for study Although the numbers were relatively small and the sample not necessarily representative, it was thought that a study of the social attributes of these children might contribute to the understanding of the mode of spread of the infection, and to the behaviour and health of the social groups concerned

It is suggested that, in communities with low standards of living, there is a widespread early subclinical infection which confers a lasting immunity to the disease, but this suggestion has not so far found general confirmation when groups with different standards are compared *within* the British Isles

In a study of these and other social factors and notified (i e , clinical) poliomyelitis between 1947 and 1950 in England and Wales, Benjamin and Logan (1953) found a pattern so complicated that they called for further inquiries into the distribution of the disease They were unable to find any correlation between the incidence of the disease and the proportion of persons in semi and unskilled occupations (social classes IV and V) or the density of housing After an intensive study in London they rejected the occupation of the principal wage earner in a family as being in any way associated with the notification rates Previously, occupational contact rather than social class had been suggested by Cowan (1950) and Logan (1953) as an important factor in the spread of clinical poliomyelitis Urbanisation (as opposed to housing density) had not been found to be associated with clinical poliomyelitis by Martin (1951)

Daley and Benjamin (1948) investigated the association of social class with notified poliomyelitis, and found no significant relationship Bradford Hill and Martin (1949) tested the association of social conditions and attack rates for poliomyelitis in 1947, using as indices infant mortality and general death rates They found no association, though there was a suggestion that crowding had played a part in the spread of the disease in London Support for the notion that social factors are important in the spread of the poliovirus, and that low standards of living (perhaps favouring early and subclinical infection) affect the pattern of the disease, comes from Daley and Benjamin (1948) who suggested that clinical poliomyelitis is less common in overcrowded conditions Several other writers have emphasised particularly the importance of standards of hygiene (e g , Benjamin and Logan 1953) Population density, economic status, and family size have also been shown by some to be associated with the spread of infection in other countries (e g , McFarlan, Dick, and Seddon 1946 Hammon, Sather, and Hollinger 1950)

Recent studies of the rate of movement of poliovirus in communities in America have emphasised the importance of the family as the site of most rapid spread (McCarroll et al 1955) , and Fox et al (1956) have shown that spread is faster in the families of Negroes than in the "lower Whites" and in the families of "lower Whites" than the "upper Whites" in the same neighbourhood That this difference in rate of spread is not only a question of family toilet hygiene has been shown by Eklund and Larsen (1956), who emphasised the importance of the oropharyngeal route of spread within the family

Further support comes from a recent study of three groups of enteric viruses (poliovirus, Coxsackie, and E C H O) where Honig et al (1956) were able to obtain relatively more positive cultures from children in poor socioeconomic groups than from children of the same age in more fortunate circumstances

The general hypothesis suggested by these studies may be stated as follows

More infection will be found in those families and social groups where there are poverty, overcrowding, many personal contacts between children, poor or inadequate sanitation and housing conditions, and many family occupational contacts More exactly, according to the hypothesis, for children of the same age, more neutralising antibody, and antibody to more of the virus types, would be expected among city-dwellers from large families of low social class, living in overcrowded unhygienic conditions or poor housing Those with many personal contacts would also be expected to have more neutralising antibody and antibody to more of the virus types

The study reported in this paper was designed to test this general hypothesis among 295 school children

Method

Results of the serological analyses of blood samples were obtained with the names and addresses of the 295 children from the university department of microbiology These analyses were available in eight categories, antibody being demonstrable for none, one, two, or all of the three types of virus From these detailed results a quantitative scale, representing the frequency or amount of infection, was derived (table I)

TABLE I—THE QUANTITATIVE SCALE POLIOVIRUS ANTIBODY PATTERNS OF 287 CHILDREN IN NORTHERN IRELAND IN 1955-56

—	Number of children with antibody pattern indicating				Total
	No infection (i e , no antibody demonstrated) (–)	Mild or infrequent infection (i e , antibody demonstrated for one type only) (+)	Moderate infection (i e , antibody demonstrated for two types only) (++)	Heavy or frequent infection (i e , antibody demonstrated for all three types) (+++)	
No of children	47	63	71	106	287
% of total	16	22	2[illegible]	37	100

---

* Late lecturer in social and preventive medicine, the Queen's University of Belfast

It was realised that certain important assumptions are involved in using such a quantitative scale for example, frequent exposures are not necessarily to more than one type of virus Its use was considered justifiable, however, as the only available measure of quantity of infection It is used in the results presented below

The social variables investigated were suggested by the literature briefly reviewed above and by the fæcal and oropharyngeal routes of spread Information about them was recorded by health visitors who did not know the serological result and who visited the homes of 287 children and asked questions from a standard interview form 8 children had moved or for some other reason were not available when called upon The information sought was of the type which could be recorded in terms such as " present " or " absent," or which required the recording of a simple statement—e g , details of the occupation of each member of the family Duplicate visits were made to a sample of the homes to confirm the reliability of the data gathered All the coding was done without knowledge of the serology The following records were made for each child

(1) *Domicile* —Children were grouped as living either in the city, in small towns, or in rural areas

(2) *Hygiene, housing, and equipment of household* —Children were grouped according to whether the house in which they lived was supplied with mains or well water, and whether the supply was inside or outside the house They were also grouped according to the presence or absence of a bathroom and washing facilities in the toilet, and of a constant hot water supply in the house

(3) *Characteristics of the household of the child* —The size of the household was noted and the occupation of each member of the household recorded in detail, the social class of the household being coded according to the occupation of the principal wage earner The breadth of the occupational contacts of each member of the household was coded by reference to occupation Thus, the child was considered to come from a household with " many " occupational contacts if any member was a bus conductor, a general practitioner, a salesman, or a shop assistant, or had a job involving many contacts with others † All other occupations were coded as " normal " It was of course recognised that the extent of the occupational contacts of an individual gives only a crude indication of the breadth of his total contacts with persons outside the family group Work contacts must, however, contribute to this total, and it was not thought practicable or within the scope of the study to attempt to measure the contacts of each member of the family outside work

TABLE II—PERCENTAGE DISTRIBUTION OF CHILDREN BY SEROLOGICAL RESULT AND AGE (UNSTANDARDISED DATA)

Age (yr)	Serological result					Test of significance of difference of serological distribution (in absolute numbers) between subgroups
	–	+	+ +	+ + +	Total	
0–3	68·2	13·6	18·2	0·0	100 (22)	χ^2 = 23·84 D F = 3 P < 0·001 (combining columns – with +, and + + with + + +)
4–6	13·9	24·7	25·8	35·6	100 (194)	
7–9	5·9	17·6	23·5	52·9	100 (51)	
10 +	10·0	15·0	25·0	50·0	100 (20)	
Total	16·4	22·0	24·7	36·9	100 (287)	

(4) *The recreational contacts* of the child were coded as " many " if the child played in the street. All others were coded as having " normal " recreational contacts.

(5) *The crowding of the family* was the number of persons per bedroom Infants were excluded from this measure.

(6) In addition, the *age* and *sex* of the child were coded.

---

† Occupations coded as involving " many " contacts were:

Bus conductors
Shop assistants
Hairdressers
Receptionists (Dentist)
Bookmakers
Customs officials
School teachers
Ward Orderlies

Receptionists (Doctor)
Usherettes
Physicians
Salesmen
Dentists
Solicitors
Messengers
Policemen

Clergymen
Counterhands in cafés
Bank clerks (counter)
General practitioners
Gas meter inspectors

Interviewers and Canvassers
Telephone engineers (domestic installation and repairs)

TABLE III—PERCENTAGE RATIOS OF THE NUMBER OF CHILDREN OBSERVED TO THE NUMBER EXPECTED ON THE NULL HYPOTHESIS, CLASSIFIED BY POLIOVIRUS SEROLOGICAL RESULT AND STATED SOCIAL FACTOR, AGE BEING HELD CONSTANT

Social factors		Serological result (%)				No of children	Test of significance of difference between observed and expected distributions
Description	Subgroup	–	+	+ +	+ + +

Other children	19	14	5	4	42
Total	47	63	71	106	287

$\chi^2 = 41.21$ D.F. = 3 P = < 0.001

Occupation and Family Infection

Table VI draws attention to a number of discrepancies —9 children who, on the general hypothesis, *should* have had little infection, but, when they were investigated, showed evidence of "moderate" or "frequent" infection. The records, however, showed that in these 9 families the occupations of the principal wage earner were general practitioner, furniture dealer and furniture-shop salesman, confectioner's shop owner and salesman, elementary school teacher, salesman in lime works, customs official, hairdresser, divisional medical officer, and electrician (house wiring). All but the last had been coded as having "many" occupational contacts. As there were only 90 families coded as having "many" occupational contacts among the 287 families represented, the probability of this happening by chance is very small (P = 0.001) and suggests that occupational contacts are important in infecting the family in certain cases.

Comment

It has long been known that countries where living conditions are poor and overcrowded, and sanitation and personal hygiene are bad, have more and earlier poliovirus infection. The present study confirms that the same pattern is found among groups with different standards within one community. Many factors may be implicated, and of those studied there is a strong suggestion that (apart from the age of the child) where he lives, the social class of his family, the extent of his recreational contacts, and the equipment of his household, all affect his chances of poliovirus infection. It has been assumed (Paul 1955) that infection by the polioviruses is through direct contact between individuals and by contamination of the environment due to poor hygiene. The importance of age, domicile, and recreational contact in the pattern of infection of the children studied could be explained in these terms by the relatively large chance of outside-the-home contacts likely to be experienced by older children, city dwellers, and children who play in the streets. Household equipment (in this case whether or not the family has constant hot water) may reflect an aspect of personal hygiene associated with the contamination of people and of surroundings. In turn, social class may cover other aspects of family hygiene as well as a variety of interacting variables such as crowding and the quality of housing. That this is not the whole story in the infection of the individual is suggested by some of the limited standardisations described above. It was found that the strength of the social class trend was almost unaffected by observing it under conditions of standard crowding or by holding constant the effect of the presence or absence of a bathroom, toilet accommodation, type and equipment of housing, or the extent of recreational contacts. This suggests that either none of these factors contributes much to the social class effect or that they are inadequate measures of contact and hygiene. Since the latter explanation appears unlikely the nature of other factors responsible for the social class trend remains problematical. We know that to measure the social class of a family is a crude way of measuring differences in environment and (perhaps more important in this context) behaviour, which are often crucial in health or mortality experience. For many other infections it is the children from the families of lower social classes which experience most disease (Registrar-General 1954). In their poliovirus infection the children in this study were no exception. But the effect on the child may not be quite the same as for other infections, for no actual illness was involved (of the 240 infected children, none had been suspected of having poliomyelitis) and all the infected children may be presumed to have some lasting immunity.

Because an infection early in life seems less likely to produce clinical disease than infection later on, one would expect that their early acquired immunity would protect the children of the lower social class families from the disease. The literature of the past hundred years and some current textbooks support this view. But the expected social class differential in mortality and morbidity was not found by Bradford Hill and Martin (1949), or by other workers reviewing notified poliomyelitis in post-war Britain. One reason for this apparent lack of social gradient could be that, though more vulnerable, the better off children were exposed less to infection. If so the expected social class gradient in the clinical disease would be apparent only after examination of the attack rates among children all of whom were known to have been exposed to infection. Such a gradient would not normally show itself in notification rates, except perhaps in the unusual situation where equal exposure of all classes of children became possible.

Summary

The pattern of neutralising antibodies to the polioviruses in 287 children in Northern Ireland has been related to the age, sex, home, social class, various measures of the type and equipment of housing, size of household, recreational, and occupational contacts, and crowding of the children and their families. None were thought to have had poliomyelitis, though 240 showed evidence of past infection.

After a series of standardisations five factors emerge as significantly and separately related to antibody pattern. Evidence of more frequent or heavier infection was associated with increasing age, life in the city rather than the small town, lower social class of family, an absence of hot-water equipment in the household, and the child having many recreational contacts. Children who showed unexpected evidence of infection came from families in which there were one or more persons from occupations (such as bus conductor or doctor) characterised by many contacts with others.

The social class of the family shows the clearest association with antibody pattern. This association does not disappear when variation due to differences in the extent of contact with others or household hygiene are held constant, and may therefore be due in part to other factors not yet investigated.

From these results it is suggested tentatively that a social class gradient in the occurrence of clinical poliomyelitis favouring the lower social class families of this group, would be expected only if all the children were to be exposed equally to infection.

This study would not have been possible without the full coöperation of Prof G W A. Dick and Dr David Dane of the department of microbiology of the Queen's University, and it is based on their investigations of poliovirus in Northern Ireland. Dr Dane was responsible for all the serology and has been a constant adviser

Thanks are due particularly to Dr W R Abernethy, Dr W Bamber, Dr J K. Kitson Dr R F McKeown, Dr. J B McKinney, Dr. W J McLeod, Dr J A. Mark, Dr B O Moore, Dr W G Swann, and Dr E. C Torrie medical officers of health and divisional medical officers of health in Northern Ireland, and to their health visitors who collected our information for us

I should also like to thank Mr W Moncrieff of the Northern Ireland Hospitals Authority, Mrs McCabe, Mr J D Merritt Mr S Crockett and Miss J Cooper for their great help in the analysis of the material, and Miss P Stewart and Miss B Ingram for clerical assistance

I am especially grateful to Dr E A. Cheeseman for his encouragement and statistical advice, and to Prof A. C Stevenson, Dr J. Knowelden, and Dr R S F Schilling for their help and to colleagues in the departments of social and preventive medicine and of microbiology, of the Queen's University of Belfast, and of public health in the London School of Hygiene and Tropical Medicine

The Minister and the Welfare Services

Addressing the local authorities' welfare conference, held in London on April 2, Mr Dennis Vosper, the Minister of Health, said that in 1957–58 57% of N.H.S. expenditure would go to the hospitals. about 30% to the general medical, pharmaceutical, dental, and ophthalmic services; and 8·3% to local-authority services. He believed that the amount allocated to the local-authority health service was not commensurate with their importance. The importance of preventive health measures and their welfare partners had been often stressed as a means of limiting the cost of the rest of the health service While he feared that the demands of the other partners in the health service would not diminish, he would try to encourage the local-authority health and welfare services, not only because it must be our general desire to keep people well and happy, but also because in the long run it should be to our financial advantage

There were, he suggested, four essentials to a successful welfare policy—that it should be local, that it should be unified that it should be centred on the family and individual, and that it should make full use of voluntary services A service which dealt with human problems must be administered by those in close contact with the people concerned It must always be not a national but a local-government service Welfare work could not be prescribed by statute and administered by regulation During the last two decades we had built up an enormous superstructure from the social services The superstructure needed so much effort and money that we might be precluded from reconsidering our social problems. With this background it was important to remember that we should concentrate more and more on the individual and the family. If at times, the superstructure or organisation did not fit the needs of the individual, then the organisation and not the individual must be changed.

Middlesbrough Award

An award (no 2646) by the Industrial Court asks the county borough of Middlesbrough to pay its medical officer of health Dr E C Downer, the salaries recommended by the regional appeals committee under the Whitley machinery

Middlesbrough has a population of about 148,000, and Dr Downer is school medical officer and port medical officer: but with successive rises in national salary scales since 1950 the corporation has always put him on the minimum salary for a local authority with a population of between 100 000 and 150 000, and it has twice ignored the strong recommendation of the regional appeals committee that, in view of his responsibilities, he should be paid at a higher rate Only under pressure from the British Medical Association did the corporation agree to arbitration by the Industrial Court It told the court that it had discretion to determine Dr. Downer's salary, within the prescribed limits, "having regard to local factors." and that, though he had given much shorter service to Middlesbrough than some other chief officers of the corporation, he received 'more cash salary' than any except the Town Clerk.

The Industrial Court's decision will perhaps restrain other authorities which may be tempted to pay no attention to what an appeals committee recommends

Mortality in 1956

Provisional figures for deaths from tuberculosis and cancer and for maternal mortality in England and Wales last year are announced by the Registrar-General [1]

Tuberculosis—The death rate for respiratory tuberculosis was 109 per million persons, compared with 131 per million in 1955 The death rate from other forms of tuberculosis was 12 per million persons, compared with 15 in 1955

Cancer—The provisional death-rate for all forms of cancer for men was 2274 per million population and for women 1891, the 1955 figures were 2252 and 1873 respectively The rise in the rate for men includes an increase from 693 to 726 per million population for deaths assigned to cancer of the lung and bronchus, the rate for cancer of the lung and bronchus for women increased from 106 per million in 1955 to 111 in 1956

Maternal mortality—The provisional rate for maternal mortality (including abortion) was 0·56 per 1000 live and still births—the lowest ever recorded

CONSULTANTS AND OTHER SPECIALIST STAFF IN HOSPITALS

THE accompanying tables have been issued by the Ministry of Health and Department of Health for Scotland as being of interest to the medical profession generally They may be of special interest to those who are intending to train as specialists All the figures relate to Great Britain

Table I shows the age distribution at June 30, 1956, of consultants and senior hospital medical officers practising in the various specialties It shows also the numbers of paid sessions undertaken by the consultants and S H M O s in each specialty for each year of birth

Table II shows the numbers of consultants in each of the specialties year by year from 1949 The corresponding figures for senior hospital medical officers are not available

Table III shows the number of senior registrars in each specialty on June 30, 1956, at the various stages of their training The column headed " Others " includes those holding " transitional " posts

TABLE III—SENIOR REGISTRARS IN GREAT BRITAIN ON JUNE 30, 1956

Specialties	Training plan					Others*	Grand total
	1st yr	2nd yr	3rd yr	4th yr	Total		
General medicine	39	40	30	27	136	68	204

A SURGICAL RESIDENTIAL COLLEGE

Viscount Nuffield and Lord Webb Johnson have long had in mind a surgical counterpart in London to All Souls College, Oxford, and their thoughts have resulted in the foundation of the Nuffield College of Surgical Sciences Viscount Nuffield gave £250,000 for the building through his Charitable Trust and helped to make available a further £187,000 from King Edward's Hospital Fund for London It is a unique institution where postgraduate students training in surgery can gather for instruction and study The college is residential, and the students mix with their fellows and their seniors, the President will have a suite of rooms there It has been in use since the beginning of this year, and all 80 places are already filled, but the official opening was delayed to April 5, the anniversary of Lord Lister's birthday

The impressive ceremony in the great hall of the Royal College of Surgeons was attended by some 500 people

To the music of a contingent of the band of the Grenadier Guards several processions entered the hall and took their seats—the council of the Imperial Cancer Research Fund, the committee of management of the Institute of Basic Medical Sciences the boards of the Faculties of Anæsthetists and of Dental Surgery, the court of examiners, and the council, with the court of patrons and some honorary fellows Then the entry of the mace heralded the president (Sir Harry Platt), with the chairman of the building committee (Mr E W Riches), Lord Nuffield, Lord Freyberg, V C, and the Bishop of London

Sir Harry Platt, P R C S, welcomed the guests and read out a brief cable of good wishes from the Royal Australasian College of Surgeons Lord Nuffield asked him to accept the Nuffield College of Surgical Sciences on behalf of the Royal College of Surgeons, and he formally accepted the gift Mr Riches presented Lord Nuffield with a book to contain photographs of the new college and of the ceremony

Lord Freyberg, in a short address, spoke of his previous associations with Lord Nuffield in connection with London House—another educational institution particularly concerned with postgraduate study—and emphasised the value to the students of the collegiate life He then walked to the door of the new building, where he was introduced to Mr A W Hall, F R I B A, the architect, and declared the building open Visitors were then at liberty to inspect the lounge, with its portrait of Lord Nuffield, and the other common rooms The students' accommodation is comfortable and the provision for recreation excellent

All too often students of medicine are denied both a liberal education and a collegiate life Lord Nuffield's bounty will now give many postgraduates a taste of residence in college, where life with their fellows from several continents must enlarge their ideas and understanding

In England Now

A Running Commentary by Peripatetic Correspondents

THE DOCTOR'S WIFE WITHDRAWS

There is no time to write—
Interrupted always by the bells
(Yes, this is the doctor's house)
The door, the telephone, or the knell
For unfortunate patients predeceased
The church is inconveniently close

There is no time
To lie close, feeling creation's surge ,
No time
To carry carefully the embryo idea,
To know its certain growth, to brood for hours
Upon its pattern
There is no time to wonder,
Intrusion hammers always at the door,
Shrilling the bells

Serenity is marred, the embryo distorted ,
With dark pain
And long drawn labour it struggles to be born
(Interrupted by the bells, of course
Even *travailing I must answer them*)
What uneven monster now will wail
Its pitiful first cry, tuneless, harsh
Into a world uninterested in birth,
Being morbidly preoccupied with death,
Atomically gigantic, yet personally minute
Or should it be
Personally gigantic, atomically minute ?
The bells distract I cannot think
There is no time even to consider
Death in this house, the bells are rung so often
To outwit it

This moron child
Incapable of receiving or returning thought
Is all I can achieve, project or leave ,
So little worth !
Yet, since there must be death,
There must be also, first, some kind of birth
(The bells know that they ring so urgently
For the newborn Doctor, quick !)
So I ll take creation's side,
Withdraw (into myself)
And leave the bells to ring !

* * *

The other day chatting to a psoriatic old woodman who attends regularly for his "skin, doctor," I found that he came originally from the village where I was born, a hundred miles away There he had been treated by my father for the same complaint over 45 years ago He was very pleased at this discovery and seemed to bear no ill-will for two generations of unsuccessful doctoring

* * *

I see that the medical correspondent of a popular newspaper has been criticised for presuming to offer a spot diagnosis of a reader's illness, based only on a letter to the paper His troubles reminded me of the more exuberant days of the 18th century, when it was quite normal for the educated patient to submit his own written case-history to a consultant, together with the fee, and to receive by return a diagnosis and an appropriate prescription

The classical example is provided by that irascible and cantankerous hypochondriac, Tobias Smollett, who undertook the Grand Tour to France and Italy in 1763-64 His continued ill health during the southward journey across France (while at Boulogne he had even, he says, ventured on the 'desperate remedy" of plunging daily into the sea) constrained him to consult a prominent local physician at Montpellier—' one of the dearest places in the south of France "—since the many English who passed that way were regarded, and for their part were content to be regarded, as generous milords with inexhaustible resources

Smollett carefully wrote out a long description of his own case, in Latin and despatched it by messenger to the great man, accompanied by *a fee of one louis'dore* (= 12 *livres*) The reply, when it came, incensed him inordinately He did not object to the doctor's recommendation of a light diet, nor to the extremely odd concoctions he prescribed for the unseen patient's alleged fever and cough , but he disagreed with the consultant's general view of the case, and most of all he took strong exception to its being couched in the French language—then regarded by many intellectuals as a semi-barbarous tongue ill-suited to the exchange of educated views

Furious, Smollett sent the doctor another note, arguing with the diagnosis ("*tabes pituitaria*," he would call it, not "*tabes purulenta* ") and implying that the case history had not been read properly The French physician stood his ground, and intimated that he would be ready to resolve *Monsieur le Consultant*'s doubts in person if he cared to call At this, Smollett's anger at once subsided He sent a note of apology, with a supplementary fee of another *louis* , the physician courteously acknowledged both , and Smollett wrote a page and a half to a friend, proving to his own satisfaction how right he had been and what a costly charlatan the doctor was

* * *

Shirley came from a large but poor family As she had collapse of the lung with bronchiectasis she was advised to have postural drainage This involved sleeping at night with the foot of her bed raised This advice was readily accepted and it was only some months later that it transpired that the whole family had to sleep with their heads down as they only had one bed There were no complaints

* * *

Awake ! But it was not morning that had flung the stone into my Bowl of Night It was young Perkins from *The Golden Lion* flinging pebbles at my bedroom window Dad's face was cut something horrible, and would I come at once The urgency of heading off old Perkins from the Dawn of Nothing penetrated my veil of sleep Still befuddled, I pulled on my pants and jacket, picked up the emergency bag, and scurried along the street Sure enough, the landlord was not a pretty sight Apart from the till, that Saturday night extension had not been an *unqualified success The takings from a rather* wild party had included turning down an empty glass across old Perkin's refusal of yet another last round He was *sitting in the bar with a dish cloth clapped to* his cheek I reckoned it needed a fair few stitches to restore some sort of acceptable cosmetic effect Mark you, Mr Perkins is not a fussy man about appearances maybe twenty years of pub-keeping dulls the finer feelings Anyway, I gave him the benefit of the doubt and infiltrated the field of operation with a spot of local anæsthetic While it was having time to act, I wandered round admiring the murals behind the bar Gamecocks and race horses to the left, cheesecake and pin-up girls to the right Perkins was certainly a connoisseur of beauty Thinking it was time to get on with the job, I leaned over the patient and inserted the first stitch Perkins flinched I wondered if the anæsthetic was all right He said it was, so I pressed on As I approached once more he drew back with a look of horror before the needle even touched him

"What's the matter, Mr Perkins ? " I snapped testily, "Surely it doesn't hurt ? Why are you looking so scared ? "

"Well, doctor," replied the victim "Have you ever seen yourself without your teeth in ? "

I glanced in the mirror over the bar Indeed my dentures lay still in the *Bowl of Night*

* * *

The French government's campaign against alcoholism is gaining momentum, and in my *carriage* on the *Métro* in Paris last week I was surrounded by such notices as

Les prescriptions de l'Academie de Medecine
Jamais plus d un litre de vin par jour !
Sante Sobriete

In the next carriage I was glad to see the more usual *advertisements* for the many proprietary brands of *attractive alcoholic beverages* Paris, tu n'as pas change

* * *

Mother (on the telephone) *Johnny has cut his head* Doctor, what shall I do ? "

Doctor (about to go out) Take him to the chemist and if he thinks stitches are needed, take Johnny to the hospital !"

Letters to the Editor

SERUM-CHOLESTEROL RESPONSE TO DIETARY FAT

SIR,—Recently we reported in your columns (Jan. 12, p. 66) the results of controlled experiments showing that dietary fat has a powerful influence on the serum-cholesterol level in man but that this is not a simple inverse function of the amount of "essential" fatty acids in the diet. In due course we shall report the detailed findings in a systematic study, continuously in progress since 1950, of the relationship of serum-cholesterol concentration to the amount and kind of fats in the diet. In the meantime it may help to reduce confusion in this area of intense research interest to disclose a major feature of the findings in 20,000 man days of controlled experiments covering butterfat, lard, olive oil, cottonseed oil, corn (maize) oil, sunflower-seed oil, safflower-seed oil, and sardine oil, as well as mixed fats in the ordinary (high dairy and meat fat) diet.

The experiments dealt with groups of 12 to 27 men at a time subsisting in calorie equilibrium on a diet adequate and constant in proteins, vitamins, and minerals in which total fats provide 9.5 to 41.5% of total calories with one or another fat being the experimental variable, usually at the level of 90–100 g. daily, for periods of two to nine weeks, averaging four weeks on each diet. The responses of the serum cholesterol level of one group of men to several dietary changes, arranged so as to control time trends, constituted an experimental series. Pertinent to the present purpose are the data from 9 such series, providing 58 sets of comparisons of diets for which we have estimates of the fatty-acid composition in terms of glycerides of saturated (S), mono-ethenoid (M), and poly-ethenoid (P) fatty acids. Except in the case of the sardine oil diet, almost all of the poly-ethenoid was linoleic acid and the mono-ethenoid was oleic acid.

We formulated the hypothesis that each of these classes of fatty acids may make a different contribution to the serum-cholesterol so that, on a given diet, the serum cholesterol concentration (in mg. per 100 ml.) would be

$$\text{(1)}\qquad \widehat{\text{Chol}}_1 = a + bS_1 - cM_1 + dP_1$$

where S, M, and P are expressed as percentages of the total calories in the diet.

On a second diet, all other things being equal, the difference between the serum concentrations of the two diets would be given by subtraction

$$\text{(2)}\qquad \Delta\ \text{Chol} = b(\Delta S) - c(\Delta M) + d(\Delta P)$$

The least squares multiple regression solution for equation (2) was obtained with the data from 41 of the 58 dietary comparisons, excluding 12 corn oil comparisons because of evidence of the peculiarity of this oil, 4 comparisons involving sardine oil because the poly-ethenoids in fish oils are so different from those in the other food fats, and one comparison of corn oil v. sardine oil.

The result was

$$\text{(3)}\qquad \hat{\Delta}\ \text{Chol} = 2.73\,(\Delta S) + 0.01\,(\Delta M) - 1.31\,(\Delta P)$$

The coefficient of correlation between the averages of the predicted and observed Δ Chol. in these 41 comparisons was r = 0.97. The contribution of the term for ΔM is statistically non-significant and recomputation with this term omitted yielded the equation

$$\text{(4)}\qquad \hat{\Delta}\ \text{Chol} = 2.74\,(\Delta S) - 1.31\,(\Delta P)$$

Since the analysis with 41 comparisons involved pooling, we attempted to examine the propriety of this procedure by obtaining separate solutions for one major series (our JWX) which provided 10 comparisons, and the remaining series providing 31 comparisons. The results were

Series	*Comparisons*	*b*	*d*
JWX	10	2.57	−1.27
8 others	31	2.68	−1.31
9 series	41	2.74	−1.31

Equation (4) was applied to the 12 corn oil comparisons and proved, as expected, to over estimate the cholesterol values on corn-oil diets, the average discrepancy being 10 mg. per 100 ml. But the application of equation (4) to the sardine-oil comparisons yielded satisfactory predictions, the mean discrepancy being only 0.2 mg. per 100 ml. or, disregarding sign, 2.4 mg. per 100 ml., which is 10% of the average observed Δ Chol.

The good agreement between observed and predicted Δ Chol. obtained here refers to averages for groups of men. Much less close agreement can be expected for individuals because spontaneous, intra-individual variation is large, even on a constant diet. Further, the analysis here is in terms of absolute units of cholesterol concentration and this is suitable because the averages of the various groups of men studied here show little dispersion on a standard reference diet. But from analyses of results with the men classified according to their serum cholesterol level on a given diet, we find the magnitude of the response of serum-cholesterol concentration to a given dietary change is correlated with the intrinsic level of cholesterol.

Accordingly we conclude that the numerical values of equation (4) apply only to persons whose serum concentration is of the order of 225 mg. per 100 ml. on an average American diet (roughly S = 19, M = 17, P = 4% of calories). With men who are intrinsically more hypercholesterolemic, the coefficients in equation (4) would be increased.

Finally, these results refer to dietary changes maintained for a few weeks long enough to complete the first phase of rapid response in the serum cholesterol concentration. Smaller effects are obtained with shorter duration of dietary change and we suggest that the magnitude of the response is a function of time so that

$$\text{(5)}\qquad \Delta\ \text{Chol} = f(t)\,[b(\Delta S) - c(\Delta M) + d(\Delta P)]$$

From some short-period experiments and from observations on populations subsisting for many years on different diets, we hazard the crude estimate that f(t) is such a function that the resulting Δ Chol. after a week of dietary change is about half that observed after three weeks, while the three week Δ Chol., in turn, may be something like half of the eventual effect produced after some years.

The result of this analysis is the indication that saturated fatty acids have, per gramme, about twice as much effect on the serum cholesterol level as do the poly-ethenoids which, moreover, act in the opposite direction. Whether the mono ethenoids (essentially oleic acid here) have any effect is uncertain, but if there is an effect it is certainly small.

A practical consequence of these findings may be illustrated by an example. It is indicated that the *addition* to a diet, as an isocaloric exchange for carbohydrate, of one ounce of sunflower-seed oil (10% and 62% of the fatty acids being saturated and linoleic acids, respectively) would be expected to lower the serum-cholesterol by an average of about 5 or 6 mg. per 100 ml. in a few weeks. The corresponding *removal* of an ounce of butterfat (57% and 4% saturated and poly-ethenoid, respectively) should produce about 3 times as much cholesterol fall. The substitution of an ounce of sunflower seed oil for an ounce of butterfat might be expected to cause a fall of a little over 20 mg. per 100 ml. in a month, *three quarters of the effect* being attributable to the reduction in butterfat. These computations are for a man in equilibrium at about 2600 calories whose cholesterol level on an ordinary (high-fat) diet is "normal" —i.e., under 230 mg. per 100 ml. In hypercholesterolemic men considerably greater responses may be expected.

Acknowledgment of our numerous obligations to sponsors, collaborators, and assistants will be made in fuller publication elsewhere.

INSULIN TREATMENT OF SCHIZOPHRENIA

SIR,—The impressive statistical results with insulin-coma treatment obtained by Dr Ackner and his colleagues (March 23) in a "controlled" trial will make heartening reading for some who still have doubts about the potential value of this method of treatment in properly selected schizophrenic patients. And I understand that the routine daily insulin-coma treatments in this particular series were often given by ever changing and sometimes quite inexperienced psychiatric registrars, or even by psychiatric nurses. Patients who might need it were also denied any further E.C.T. during the course of their insulin-coma treatment, and only 30–40 comas were given to patients; whereas we know from Polonio's ten-years statistical study of insulin coma treatment that such a low number of comas can markedly reduce the number of successful results obtained.[1]

The excellent results reported despite these drawbacks, therefore, suggest what can be achieved with insulin-coma treatment when given by highly trained and experienced therapists in properly selected patients, and when it is combined with all the other methods likely to be needed, including the new tranquillisers, psychotherapy, and E.C.T. given during the course of insulin treatment. It also makes more understandable why its use has grown in this country ever since it was introduced twenty years ago.

It is also not very surprising that the use of daily barbiturate comas followed by strong brain restimulation with dexamphetamine also produced almost equally good results as those obtained in this particular insulin group, though no less than four out of twenty-five patients may need to remain in hospital as chronic patients because a barbiturate induced coma was substituted for insulin comas.

Do many experienced therapists really believe, as Dr Ackner and his colleagues suggest they do, that insulin is the specific agent of recovery in insulin coma treatment? If so, why does not modified insulin treatment work just as well? Over the past twenty years, as one has continued to use this treatment, one has seen time and time again how really deep comas may help a patient when less deep comas have failed to do so, and "irreversible" comas can sometimes produce the most dramatic results of all. This is why really skilled insulin therapists are needed to get the best results with this particular treatment. It is probably the combined sedative and the stimulating effects of the coma itself that matters, and not the giving of insulin per se, just as in E.C.T. it is the convulsive brain fit that is really important and not the electricity that produces it. Gain in weight, helped by insulin, may however contribute to the stability of recovery, and this could possibly help to explain why four more patients were able to leave hospital even in this particular insulin group as opposed to the barbiturate coma group.

What these authors also did not tell us was that Russian workers have used methods resembling their so-called "control" method as an alternative and successful physical treatment of schizophrenia. They have, for instance, reported the value of repeated narcotic treatments with 'Sodium amytal' and other barbiturates combined with subsequent restimulation of the brain by caffeine, fever therapy, convulsion therapy, and therefore also, presumably, by dexamphetamine. Reports on the use of such methods in schizophrenia appear in Wortis's book.[2]

As long as I have known him, Dr Ackner has been suggesting in conversation and discussions that the beneficial effects of insulin coma may be due much more to the group psychotherapy of the total insulin regime than to the actual physical treatment used. I have no doubt that this supposed "control" group was meant to try and throw more light on this matter, and he refers to the possible psychotherapeutic effects of insulin coma treatment in discussing these results. But this paper really provides very little evidence either way on this point, for Dr Ackner and his colleagues have so unfortunately chosen for their "control" group a method which resembles successful Russian physical treatment methods in schizophrenia, based on carefully controlled pavlovian physiological research.

Having often suggested that it could be the psychotherapeutic aspects of the insulin régime that really mattered, why did not Dr Ackner have the genuine courage of his convictions and use sterile water instead of this powerful and very physiological barbiturate-amphetamine combination for the control group? Then we might have really learnt something on this important point. We do know that a good atmosphere in an insulin ward is very important, whatever depth of coma is given, but I doubt whether it is really as important or gets patients well as quickly and as easily, as the giving of really deep and skilled comas, combined with E.C.T., psychotherapy, and the tranquillisers when necessary. Certainly I hope we are not going to go back (unless the evidence becomes statistically and clinically absolutely overwhelming) to too much loose psychological theorising about the treatment of schizophrenia; for we have come so far in the past twenty years using all these new physical methods, compared to the days when all we used to have at our disposal were the many and varied types of psychotherapy which all proved so very disappointing, when used *alone*, both inside and outside mental hospitals.

London W.1. WILLIAM SARGANT

SIR,—We have read with interest the controlled study of Dr Ackner and his colleagues on insulin treatment of schizophrenia. We feel, however, that their criteria for the choice of case grouping, based as they are on clinical psychiatric data only, are open to question. Our own studies[1,2] point to wide physio-pathological differences among cases of schizophrenia with similar psychiatric symptomatology. It would therefore seem that giving insulin coma therapy to schizophrenics in groups selected only on a clinical psychiatric basis may in fact be treating cases of widely differing physio-pathological make-up. It would not be out of place to compare insulin treatment given in this way to prescribing, shall we say, a certain convex lens to all those who complained of some defect of vision.

In studying schizophrenics who apparently formed a homogeneous group from the clinical psychiatric aspect we found,[2] for instance, that in the group there were patients with high adrenocortical function who reacted well to deep insulin coma treatment, at least temporarily, and others with decreased adrenocortical function who usually failed to improve with insulin comas and sometimes deteriorated. We could quote other examples of groups apparently homogeneous on clinical assessment that were heterogeneous from the physio-pathological aspect. We should also infer that any homogeneity in the groups studied by Dr Ackner and his colleagues was related much more to the genetically conditioned personality-pattern of the patients than to their physio-pathological state which determines their response to treatment.

It seems to us that progress in the classification or treatment of the schizophrenias cannot be expected so long as the criteria used by clinicians fifty years ago are still accepted and applied without further investigation or revision. If it were possible to reasthe data in the paper by Dr Ackner and his co workers on a physio-pathological basis, we feel that conclusions would be reached that might be more valuable for both present use and future progress than those stated by the authors These new conclusions might also give some insight into the value of a therapy which has mainly been used empirically in the past, but should now be applied on a more rational basis In our view, their approach to the problem of insulin-coma therapy endangers the continued use of this treatment in at least one group of schizophrenics—viz, namely with high adrenocortical function—for whom it cannot yet be replaced

---

THE FLOPPY INFANT

Sir,—I look to your annotations to clarify my thoughts and your remarks of March 30 (p 678) very properly alert me against making a generalising diagnosis of amyotonia congenita to cover up a multitude of somewhat similar conditions Amongst the alternative diagnoses put forward, however, we come across mental defect side by side, of course, with cerebral palsy—its only chance of equality with it, alas, as things are at present

What is mental defect ? If it is a diagnosis it is certainly a much more nebulous one than amyotonia congenita wrongly applied There should be no such diagnosis as mental defect It is simply a symptom of an underlying physical disability and, until you, Sir, and all other doctors realise this, the "mentally defective" child will continue to be the most ignored, least investigated, and worst treated patient in the community

Twenty years ago the cerebrally palsied, the phenyl ketonurics, and the victims of maternal rubella were all merely "mentally defective" One might say many of them still are but, at least, we are looking scientifically at them the other way round !

Let us give the same attention to the still unknown causes of the end-result and never, when we are unable to find anything else except "mental defect," accept that as a specific diagnosis or as final evidence of an irremediable condition treatable only by inaction, sedation, or segregation

Chertsey J M Crawford

DEPOT TUBERCULIN

Sir,—In contrast to Dr Hall (March 2), we have found that the use of tuberculin in a depot vehicle increases its sensitivity considerably

Comparative testing in adults from 30 to 50 years of age, has shown that depot tuberculin gives positive reactions with doses as low as 1/250–1/20,000 of the threshold dose of aqueous tuberculin[1] This greatly increased potency of depot tuberculin has been confirmed by Citron,[2] who obtained positive reactions to 6 T U depot tuberculin in tuberculous patients who had been thoroughly desensitised to tuberculin and who did not react to Mantoux testing with 100 T U aqueous tuberculin

Two age extremes are represented by the predominantly newborn and infants reported on by Dr Hall, and the elderly subjects reported on by Dr Kolcan and Dr Beresford (March 16) Reactions to depot tuberculin may differ in these age groups from those in adults of young and middle life We have found that reactions to depot tuberculin develop more slowly in elderly and aged subjects taking 7 or more days to appear in contrast to the usual 2–3 days

Like ourselves, Dr Kolcan and Dr Beresford did not have difficulty in distinguishing between reactions elicited by the depot tuberculin as compared with the control vehicle We preferred the soft thin skin of the outer upper arm for our tests and found that control tests, carried out in all the cases, gave reactions which were negative or insignificant The long persistence of the oily vehicle leading to reactions which may last for three months or longer in more sensitive subjects is, of course, a disadvantage if considered for routine testing The principle, however, of a "depot" tuberculin stands to gain, from this long persistence, for the study of the development of hypersensitivity in previously negative subjects Alternative vehicles may be better suited for this purpose

ATHEROSCLEROSIS AND VITAMIN B_{12}

Sir,—Oliver and Boyd's[1] emphasis on the part played by the hormones in atherosclerosis, and the more recent address by Morris,[2] tending to discount dietary fat as the main cause, have prompted me to describe, perhaps prematurely, my own findings with vitamin B_{12} (cyanocobalamin)

It had already been noted that, after a variable lag period, both vitamin B_{12}[3] and liver[4] appear not only to desensitise the allergic, but also to cause, in the presence of secondary infection, an increase in membrane permeability[3] At about the same time, it was also observed that 8 of my patients, who were all suffering from obvious atherosclerosis, and who had all been given vitamin B_{12} as a tonic (50 µg orally thrice daily), were all significantly and obviously worse, again after a lag period of similar duration—4–21 days

As a control, a further group of 6 patients also suffering from obvious atherosclerosis, and of a similar age group, were then maintained on control tablets over a period of one month During this time, they were kept under close observation 2 appeared to improve, 3 showed no change, and 1 showed some deterioration—i e, increased dyspnœa There was no severe clinical deterioration, such as the onset of angina pectoris intermittent claudication or "rest" pain as occurred in the group treated with vitamin B_{12}

After due consideration of these findings, it was decided that all patients suffering from atherosclerosis, should be treated as follows

(1) A lactovegetarian diet was strongly advised, emphasis being placed upon the necessity for increasing the patient's intake of vegetable protein and upon the need for as large a variety of cereals, vegetables, and fruits as possible Milk intake was limited to one pint per day for all purposes and all other casein containing milk products especially cheese, were excluded Animal fats were permitted and a timely warning against possible weight gain was given If there was any risk of congestive failure egg albumin (the yolk being excluded) was recommended as an added source of animal protein

(2) The patient was given orally 50 mg of ascorbic acid four times daily

During the past three years, 33 patients have been treated by this method 29 have shown a significant improvement in symptoms and signs, thus after a period of three to four weeks, they could walk further and faster and their legs, if cold initially, regained their normal skin-temperature

During these three years 12 patients failed to maintain their diet and all 12 relapsed 7 resumed the diet and have since improved again, 1 refused to maintain the diet and has since died of congestive failure and the other 4 of this group have only recently resumed their diet

---

[1] Oliver, M F, Boyd G S *Lancet* 1956 ii, 1273

[2] Morris J N See *Ibid* Feb 23 1957 p 410

[3] Annand, J C *Practitioner* 1955 175 725

[4] Moll H M *Brit med J* 1932 i 976

The remaining 4 patients maintained the diet for a short period only, 1 has died of coronary thrombosis, 2 have survived a second coronary thrombosis, and 1 has had a cerebral thrombosis

A patient, who had had a bilateral lumbar sympathectomy for endarteritis obliterans, and who also suffered from angina of effort, admitted only slight increase of painless walking distance, in spite of strict adherence to the diet Later he resumed normal diet and survived a coronary thrombosis three weeks later

A correlation between intake of animal protein and atherosclerosis does appear to exist Thus, the people of Italy[5] and the Bantu of South Africa,[6] who both consume a diet low in animal protein, and also vegetarians[7,8] per se, are all relatively free from atherosclerosis On the other hand, there is the apparent contradiction that the meat eating Eskimo does not develop atherosclerosis[9] The comparison is not a true one, however, since the uncivilised Eskimo eats no fruit or vegetables and little or no fat (used for heating or lighting purposes) and consumes his meat entirely raw, thereby obtaining the advantage of all of its vitamin content At the same time, he, unlike the European, is subjected to long spells of near or complete starvation, a condition which has been found to double the urinary excretion rate of vitamin B_{12}, but not that of folic acid or of the citrovorum factor[10] Moreover, unlike the civilised Eskimo, who cooks his meat, he never gets scurvy, in spite of the complete absence of fruit or vegetables[9]

The following points also appear to be significant

(*a*) The urinary excretion rate of vitamin B_{12} has been found to diminish with advancing years,[11] whilst the serum cholesterol level, which vitamin B_{12} appears to control,[12,13] seems to increase concurrently[14]

(*b*) Both vitamin B_{12}[3] and animal protein[15,16] (not devitaminised) have been found to increase membrane permeability

(c) Finally, both reduced glutathione[17,18] (which vitamin B_{12} *appears to maintain catalytically in the reduced state*[19]) and vitamin B_{12} block the action of the glucocorticoids in both the animal[20] and the human[21] thereby possibly permitting the opposing action of the mineralocorticoids

To summarise, some circumstantial evidence, derived *mainly from clinical observation and partly from published* work, suggests that, after a variable lag period, vitamin B_{12} makes the symptoms and signs of patients with atherosclerosis much worse The existence of this lag period has made it difficult to prove cause and effect and medical ethics forbids a deliberate trial But a diet low in vitamin B_{12}, again after a lag period of three to four weeks, did appear to be of significant value in this limited series

CHRONIC BRONCHITIS AND SMOKING

SIR,—I am inclined to agree with Dr J P Anderson (March 30) that it was surprising that more mention was not made of cigarette smoking in the course of the N A P T Symposium on Chronic Bronchitis held last December The N A P T invites speakers to give their personal opinions at such gatherings, and does not put words into their mouths

The N.A P T leaflet "Bronchitis" is designed to give advice, in a persuasive manner, to those who need it There is no need to urge the non smoker to abandon cigarettes Only those who enjoy smoking have to be persuaded that it is in the interests of their health to give up what is, to them, a source of pleasure We shall be more *successful* in our propaganda if we admit that, to those who smoke cigarettes, smoking is an enjoyable habit

The *N A.P T Bulletin* for December, 1956, contains a statement by the N A P T council on smoking and lung cancer, and a memorandum of scientific evidence in support of the views expressed with which I am sure Dr Anderson would fully agree This can leave no one in doubt about the attitude of the N A P T towards the dangers of cigarette smoking

ÆTIOLOGY OF PRE-ECLAMPSIA

SIR,—During recent years, Mr Sophian has written extensively about his theory of a uterorenal reflex as a cause of pre eclampsia He has claimed additional points, including our own studies,[1,2] which he believes confirm his theory The majority of these claims have passed completely unchallenged and hence it may have been assumed, particularly abroad, that many obstetricians accept Mr Sophian's views For this reason I should like to review briefly the essential arguments *that have been* advanced to support the theory of a uterorenal reflex It may then be clear why, to many, they appear unconvincing

A primary stimulus is presumed to arise from the myometrium as a result of the uterus adapting to its *contents* and producing thereby "increased myometrial tension," or alternatively "myometrial resistance to stretch" Proof of increased tension can be derived, according to Mr Sophian, from (*a*) biochemical studies and (*b*) tocometric tracings However, it is not yet finally established that such methods do provide an efficient index of myometrial tension Furthermore, results obtained by using such measures have not confirmed a *consistent* increase in myometrial tension in cases of pre eclampsia Surely this initial criterion must be satisfied before assuming that myometrial tension is even associated with, let alone is the cause of, pre eclampsia

Mr Sophian also claims that intra uterine pressure has little relationship to myometrial tension, but, once again this is open to serious dispute This further assumption allows him to explain away why there is no consistent association between raised intra uterine pressure, as in twins, acute hydramnios, pregnancy in a rudimentary horn, and pre eclampsia

The kidney is thought to respond *to this* uterine stimulus in a way closely resembling that described originally by Trueta et al[3] in animal experiments and it is this renal reaction that finally fires off the syndrome that is recognised as pre eclampsia The extent *of this* reaction is said to be governed by the "responsiveness" of the kidney This again conveniently allows Mr Sophian to postulate that the renal response is often not propor

---

1 Morris N Osborn S B Payling Wright H *Lancet* 1955 i 323
2 Morris N Osborn S B Payling Wright H *Ibid* 1956 ii 481
3 Trueta J Barclay A E Daniel P M Franklin K J Prichard M M L Studies of the Renal Circulation *Oxford* 1947

tional to the uterine stimulus This kidney reaction is completely incapable of reliable assessment, at least by measures so far at our disposal

Essentially, therefore, Mr Sophian postulates a cause (increased myometrial tension) for which there is at present absolutely no reliable evidence and an effect (renal shunt) which cannot even be measured

Animal experiments [4] do suggest that experimentally a form of uterorenal reflex can be established. There is no evidence that this in turn establishes a *clinical* picture comparable to pre-eclampsia

Severe concealed accidental hæmorrhage is often associated with extensive renal damage This reaction would therefore suggest a clear-cut uterorenal association in this condition Furthermore the kidney changes bear some resemblance to those described by Trueta However it is not yet clear whether these are the result of a reflex or of the liberation of a toxic substance from the utero-placental site The suggestion by Page and Glendening [5] that there could be a sudden liberation of serotonin or a similar substance seems a distinct possibility Few clinicians will find it possible to accept that the pathological changes in pre eclampsia and concealed accidental hæmorrhage are the same, and only differ in matter of degree

Finally, Mr Sophian explains away pre-eclampsia occurring in association with a late extra-uterine pregnancy by claiming that "blood and certain other substances spilled on the peritoneum can provoke a renal shutdown" This is indeed a bitter pill to stomach Why then does not pre-eclampsia occur in association with a ruptured ectopic gestation or corpus luteum, hæmorrhage from an ovarian cyst, or any condition causing peritonitis or peritoneal irritation in pregnancy?

I am sure that Mr Sophian will conjure up a further hatful of ingenious explanations, but until he provides reliable direct evidence in support of all the claims he makes, I shall continue to regard his theory as compounded of a mixture of assumptions and exceptions

NORMAN MORRIS

BURNS AND SCALDS

SIR,—The time is surely overdue for Professor Wardill and his colleagues in Baghdad to publish a full description of their method of treating burns Baghdad is admittedly only a few hours distant by air, but few of us have the financial resources to accept their invitation to see for ourselves The meagre details so far available excite intense curiosity, and their curt dismissal (March 16, p 588) of Mr Watson and Mr McLaughlin's well-reasoned letter [6] with a hypothetical Shakespearean quotation heightens the mystery

Professor Wells [7] has attested that granulations of an unusual quality are produced But now we learn—and here is the hub of the mystery—that only 1 case in 80 has been grafted This immediately suggests that the remaining 79 were superficial burns Why then the emphasis on the production of granulations?

Granulations as we understand the term, form only after full-thickness destruction of skin If ungrafted, they can heal only by ingrowth of marginal epithelium a lengthy process accompanied by scarring and contracture It seems unthinkable that this should be what Professor Wardill advocates Perhaps the explanation lies in the word "granulations" Are those of Baghdad merely the surface appearance which results when superficial burns are treated by exposure in a tropical climate? Or is there an element of mid oriental magic involved?

Professor Wells's enthusiastic letter on this method of treatment and the recent visit of his colleague, Mr J H Johnston, to study the technique have provided excellent advance publicity, and we hope that Professor Wardill will not long delay a fully detailed exposition

Glasgow Royal Infirmary

THOMAS GIBSON
IAN A McGREGOR

THE Rh BLOOD-GROUPS

SIR,—The letters of Dr Nicholas (March 2) and Dr Sheppard (Jan 26) cannot be allowed to stand unchallenged

Dr Nicholas now writes "I did not say that the use of 'most likely genotypes' leads to paradoxes—far from it" But "most likely genotypes" does lead to paradoxes, as I have shown, because it sets an unnecessary trap, and when there is a trap somebody falls into it Why use "most likely genotypes" at all when you can use separate designations for phenotypes and genotypes? In fact, there is a tendency among C-D-E protagonists to drop the phrase "most likely" and to speak of "*genotyping*" when *all that is really done* is Rh-Hr *phenotyping* I have already pointed out how Buchanan fell into the trap, and now Renton and Hancock [1] provide another example

They have written an entire article describing what they consider to be a new variant of factor Rho, and which in contrast to factor Rho renders blood cells more agglutinable by anti-Rho sera What they may actually be dealing with is probably a gene dosage effect Thus, their findings are readily explained if one assumes that the highly reactive bloods which they designate as CDe/cde and cDE/cde are really CDe/cDe and cDE/cDe, respectively In Renton and Hancock's paper, significantly, the phrase "most likely" has been dropped, just as in Race and Sanger's book If separate phenotype and genotype symbols had been used, as in the Rh Hr nomenclature, this blunder would not have been made

Dr Sheppard accuses me of not understanding the C-D-E notations, while Dr Nicholas charges me with being inconsistent They are both probably correct In fact, how can anyone understand or be consistent when discussing a subject matter like the C-D-E notations, which are inherently illogical, inconsistent, and self-contradictory? For example, will Dr Nicholas kindly *resolve the following* contradictions which puzzle me

1 In place of the Rh-Hr symbol Rh_1rh, I have seen the following C-D-E symbols used C—D+E—c+, CDe/cde, CcDe, CcDee, CDe/c, DCe/c, CDeF/cdef, or as Ford has suggested, *C*(A—B+), D(A—), E(A—*B*+) Which of these is the "official" designation, or have I failed to include the "correct" one in this list?

2 Blood cells lacking both factors of the pairs rh′ hr′ and rh″ hr″ are attributed to gene deletions (–D–/–D–), but blood lacking both factors of the pair S–s are ascribed to a special allele S^u This raises the question, how does one decide when to postulate a "deletion"?

3 One argument raised by C-D E protagonists against using symbols like R^1R^2 is that such symbols are difficult to understand Yet R_1R_2 is used by them as a short symbol for CDe/cDE Please explain on what basis R_1R_2 becomes related to CDe/cDE, and why R_1R_2 is more intelligible than R^1R^2?

4 On pp 129–130 of the 2nd edition of Race and Sanger's book [2] appears "The finding of the remaining antibody, anti-*d* was first reported by Diamond in 1946 Two further examples were reported by Hill and Haberman Thus the theory of Fisher has been confirmed in all its predictions"—*But on p* 181 these authors write about the Hill and Haberman report "Now that anti *f* is commonly found in anti-c sera we feel doubtful about the identity *of these* two examples of anti-*d*" Please reconcile these two contradictory statements in Race and Sanger's book

5 The supposed gene arrangement DCE was based on the statistical test $R = r' - r'' - R^z$ Race and Sanger now admit

---

[4] Franklin K J Winstone N E *J Obstet Gynæc Brit Emp* 1955 62 29

[5] Page E W Glendening M B *Obstet Gynec* 1955 5 781

[6] Watson J McLaughlin C P *Lancet* 1956 ii 685

[7] Wells C *Ibid* p 577

[1] Renton P H Hancock J A *Brit J Hæmat* 1956 2 295

[2] Race R R, Sanger, R Blood Groups in Man Oxford 1954

(p 170) that "it is possible to pick results strikingly in favour of the cross-over idea—*and strikingly against it*" [italics mine] How then can one justify the position of Race who continues to speak of the gene order DCE ?

6 Since, as Race and Sanger admit (p 171), "It does not seem unfair to say that anthropological results have been inconclusive," they have abandoned the cross over hypothesis and now postulate "completely linked genes" or "pseudoalleles" If there is no crossing over and no "deletions," how does one determine the order DCEF ? Also, what is the difference between a completely linked set of genes and a unit gene ? And what exactly is the difference between the concept of complete linkage and Wiener's theory of multiple alleles ?

7 When calculating gene frequencies, Fisher and Race use the complex maximum likelihood method in order to achieve an increase in accuracy affecting the third or fourth significant figure, but at the same time they use "most likely genotypes" which entail errors as high as 15% Please explain this inconsistency

8 Symbols like anti-D+D^u, anti C+C^w, and anti-A+B are used by C D E protagonists to designate antisera supposedly containing "linked" antibodies Please explain how one decides whether one is dealing with "linked" antibodies or a single cross reacting antibody Also please explain how one knows whether the symbol represents "linked" antibodies or a polyvalent serum like anti C+D and anti-D+E

In closing I should like to emphasise again that the basic fallacy in the C-D-E notations is the failure to recognise the distinction between a blood factor and an agglutinogen[3]—a concept as fundamental for blood-group serology as Newton's laws of motion are for mechanics Unless this concept is understood, no worker may expect to master completely the science of blood-grouping

It is time to stop teaching this C-D-E nonsense, and to teach the Rh-Hr nomenclature exclusively But, as shown by the letters of Dr Nicholas and Dr Sheppard, it is far more difficult and painful to unlearn something which is wrong than to learn a subject correctly in the first place

Brooklyn, New York, U S A A S WIENER

THE STAPHYLOCOCCUS PLAGUE

SIR,—In your leader last week you say that the heart of the problem is the presence of nasal carriers of antibiotic resistant staphylococci, and that this is due to uncritical use of antibiotics in hospitals

If this thesis was true, swabbing all personnel and treatment of proved carriers with effective anti staphylococcal agents would surely abate the plague In practice, these measures, though helpful, are not a cure

Antibiotic resistant staphylococci enter a hospital in the body and fomites of a patient Thence they are disseminated by handkerchiefs, discarded dressings, the fingers of attendants, discarded clothing and personal effects, and coughs, sneezes, and discharges Staphylococci are very hardy organisms, and can survive unharmed for long periods in room dust, in the interior of pillows and mattresses, in blankets, and in patients' personal belongings kept in bedside lockers Because the sensitive strains of staphylococci have succumbed to the treatment of the patients with antibiotics, only insensitive strains survive, and these insensitive strains populate the foci detailed above

The provision of an air-conditioned room is excellent advice would that it could be implemented ! The brutal realities of the situation, however, reveal that much less expensive improvements are cancelled merely on the grounds of cost

For instance, the provision of effective masks and sterile gowns for all nurses in the wards and the provision of thin rubber gloves for all nurses handling infective material (e g, bedpans, the bottoms of infants with gastro enteritis, soiled napkins, soiled dressings, soiled linen, and soiled handkerchiefs, to mention only a few examples) is too expensive

The provision of covered bins for the bedside disposal of dressings, the routine treatment of pillows with moist gaseous formalin in the hospital steriliser (or the use of a 'Sparkhall'), the routine treatment of mattresses with formalin in the hospital steriliser (or the use of a sparkhall), the treatment of blankets by washing in 'Lissapol' followed by soaking in 'Fixanol', and the anchoring of bacteria laden dust particles on the floors, &c, of wards, all these simple, effective and relatively inexpensive measures are neglected The reason given is that these measures add to the cost of hospital administration

Actually one of the most expensive items in a hospital budget is the drug bill Antibiotics are the expensive items A small sum spent on banishing resistant staphylococci from the bedding and dust of hospital wards would be more than repaid in the saving in antibiotics that would follow Administrators cannot see this

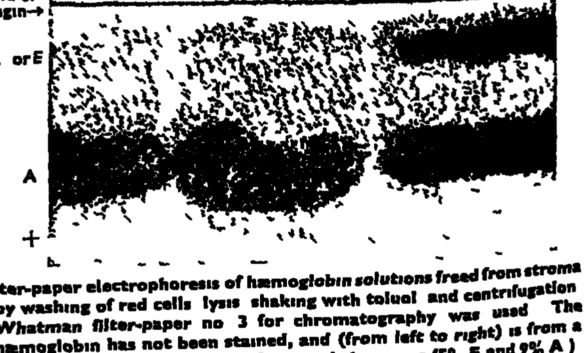
St Margaret s Hospital,
Epping FRANK MARSH

THE RECOGNITION OF HÆMOGLOBINS A_2 AND E

SIR,—There are now known two pairs of hæmoglobins with identical electrophoretic properties sickle cell hæmoglobin (hæmoglobin S) and hæmoglobin D, and hæmoglobins E and A_2 A survey of a population for the distribution of hæmoglobin variants merely by electrophoresis of blood specimens will therefore fail to differentiate between S and D and between E and A_2 respectively

In the case of S and D, differences in the solubility of the ferrohæmoglobin allow a separation Hæmoglobin D does not cause the sickling phenomenon when red cells are deoxygenated in vitro, and the routine test for solubility of reduced hæmoglobin in 2 24 M phosphate buffer devised by Itano[1] easily establishes whether S or D is present

Hæmoglobin A_2 is found in small amounts in normal people, but its proportion is raised in thalassæmia[2] Although the techniques usually used to demonstrate hæmoglobin A_2 are open boundary and zone electrophoresis, raised amounts can certainly be recognised by routine paper electrophoresis[3,4] (see accompanying figure) Even normal amounts can be demonstrated by paper electrophoresis when thick paper is used, and when large amounts of hæmoglobin are applied to the starting line If small amounts fail even then to be visible on the unstained paper, they can be made visible by staining



Filter-paper electrophoresis of hæmoglobin solutions freed from stroma by washing of red cells lysis shaking with toluol and centrifugation The Whatman filter-paper no 3 for chromatography was used The hæmoglobin has not been stained, and (from left to right) is from a normal individual (3 5 %A), from a thalassæmic (5% F and 9% A) and from an Eti Turk with hæmoglobins A and E (no F, 40% E) with a protein dye There is therefore a possibility of mistaking the electrophoretic pattern of the hæmoglobin from a thalassæmic for that of hæmoglobin AE heterozygote

---

[3] Wiener, A. S , Wexler I B *Bact Rev* 1952, 16, 69

[1] Itano, H A *Arch Biochem* 1953, 47, 148

[2] Kunkle H G , Wallenius, G *Science* 1955 122 288

[4] Crowley M F , McSorley, J G A Aksoy, M , Lehmann H *Vox Sanguinis* 1957, New Series 2, 53

We should like to point out that there seems to be a rule according to which the proportion of E in a heterozygote for hæmoglobins A and E does not fall below 20%, and that the proportion of A_2 in thalassæmia does not rise above 15% This rule is fairly general, though we have seen one exception If this differentiation is adhered to, serious errors will be avoided in mass surveys In individual cases other features characteristic for thalassæmia can of course be sought for to establish the diagnosis

Some of our surveys for hæmoglobin E were carried out before Kunkel's A_2 phenomenon had been fully appreciated We have therefore reviewed our previous surveys of populations in which the genes both for thalassæmia and for hæmoglobin E are found, and by taking due account of this rule we have come to the conclusion that we have no reason to correct former reports on the incidence of hæmoglobin E either in isolated instances in Turkey or in larger numbers in South-East Asia

We want to thank Dr H G Kunkel, of the Rockefeller Institute for Medical Research, New York, for advice and discussion and for confirming our results when we measured A_2 either directly following elution from starch after zone electrophoresis or indirectly following elution of protein dye from the stained paper after paper electrophoresis

GASTRO-ENTERITIS IN UGANDA

SIR,—Your annotation on my paper[1] is quite correct in pointing out that simple clinical pathological tests can never be a complete substitute for more advanced bacteriology in this disease This particular study was, in fact, limited to ascertaining what information could be obtained from stool microscopy, and attempted to correlate this with the result of treatment and with such bacteriology as was then available to us It must be remembered, of course, that for a long time to come most tropical hospitals will not be able to carry out more than the simplest bacteriology and many can do none at all

Following on this, a further study was undertaken by Dr A M M Wilson and myself in which more detailed bacteriology was carried out and which does, in fact, set out to answer the points you raise concerning the efficiency of rectal swabs, the value of direct ward plating of swabs, and the use of carrier media in transportation to laboratories The results of this study, shortly to be published,[2] confirm the scarcity of *Escherichia coli* serotypes, which you suggest, and the preponderance of shigella infections

The Hospital for Sick Children
London W C 1
J LUDER

GOVERNMENT AND PROFESSION

SIR,—Your leading article of March 30 is by far the most important statement that has been made on the present regrettable state of British medical politics, it should be carefully studied by general practitioners, consultants, Ministry officials, Members of Parliament and, above all, by the leaders of the British Medical Association

You, Sir, expose clearly and objectively the absurdity of the threats of a doctor's strike (for temporary withdrawal is a strike) and you show how much we as a profession will lose by aping the methods of industrial trade unions

It is beyond doubt that a good case can be made for the improvement of doctors' working conditions in the Health Service We can best establish this case by a sensible and reasoned propaganda in the press and Parliament and by cooperation with the Government of the day—in other words, by the methods of an enlightened democracy

Parliament

THE ROYAL COMMISSION'S TERMS OF REFERENCE

ON April 4 Lord MORAN asked the Government whether they were satisfied that the terms of reference of the Royal Commission on the professional remuneration of doctors and dentists in the National Health Service would provide the necessary basis for a full examination of this problem

SPENS PAST AND FUTURE

He recalled that in the early days of the National Health Service the two Spens Committees were appointed by the Government to deal with the remuneration of general practitioners and consultants respectively Summarising Ministerial statements on the recommendations of these committees he reminded Noble Lords how in July, 1946, the permanent secretary to the Ministry of Health wrote to the British Medical Association "The Minister fully accepts the substance of the recommendations" Three years later, in January, 1949, the parliamentary secretary to the Ministry said in the House of Commons that the remuneration of general practitioners would be adjusted to give effect to the Spens recommendations In May, 1950, the permanent secretary to the Ministry wrote a letter saying "The Minister agrees that the Spens Report remains the basis of the remuneration of general medical practitioners until such time as after the usual consultations some other basis is substituted"

As a member of one of the Spens Committees Lord Moran could testify that the recommendations were then interpreted in the same way both by the Government and by the doctors Yet Lord Salisbury, in announcing the Royal Commission, said that the interpretation put upon the Spens reports by the profession could not be accepted by the Government The Government appeared to have first expressed doubts about the interpretation of Spens when a Judge of the High Court, Mr Justice Danckwerts, awarded the general practitioners £40 million in 1952 From that day until now the Government had been anxious to get rid of Spens Mr Attlee's Government, Lord Moran continued, might have been ill advised to accept these recommendations, but the fact remained that they did accept them, and that it was upon that acceptance that many doctors entered the health service In these circumstances he thought Noble Lords might feel that these recommendations could not be thrown on the dust heap because they had proved inconvenient

If the Royal Commission interpreted their terms of reference so that they were not required to pay regard to what had happened in the past, and dealt merely with future scales, then in his view they were wasting *their time*, they would not allay the discontent among the doctors, nor would they provide a lasting solution of this question of remuneration He pressed the Government to say whether the Royal *Commission* would or would not take into account the Spens reports

When the doctors went into the service they understood clearly that the cost of living would be taken into account when their pay was reviewed from time to time Nevertheless, Lord Moran trusted that the doctors would *not* try to bind the Government to a literal interpretation of Spens in perpetuity He admitted that this provision would excite the wrath of a section of the medical profession, but if there was to be a settlement satisfactory to the Government and to the doctors, there must be give and-take on both sides If the doctors were to give up the literal interpretation of Spens—namely, that every rise in the cost of living would be met by a rise in their salaries—then they were surely entitled to some quid pro quo What was needed even more than a rise in pay was some reformation of the arbitration machinery At present, a dispute between the consultants and the Government was referred to Whitley Council B This consisted of two halves, the doctors and the officials of the Ministry, and only if they agreed, could a dispute go to arbitration But in all matters of substance they never did agree The Government saw to that The result was that the consultants generally had lost confidence in this machinery What would they accept in its place? A special advisory committee lately appointed by the Prime Minister to supervise the pay of the higher ranks of the Civil Service was precisely what the specialists needed

AWARDS AND MERIT

Turning from the future and its possibilities to the present and the Royal Commission, Lord Moran suggested that it was inconsistent of the Government to press every section of the community to go to arbitration except the doctors Could Noble Lords imagine the Minister of Labour facing the shipping and engineering industries, when they are asking for a rise in wages, and fobbing them off with a Royal Commission? The doctors felt that they were being treated differently because they had no political power, and that produced bitterness Nor were the doctors better disposed to the idea of a Royal Commission when, on Feb 20, the Minister said to the representatives of the Negotiating Committee that if the Royal Commission found in the profession's favour, and if the economic situation of the country remained the same, it by no means followed that anything would happen Apparently, the findings of this Royal Commission were to be taken seriously only if they were in the Government's favour

But what really aggrieved the doctors were the terms of reference Royal Commissions were generally free to gather information wherever they could find it "All relevant factors" was almost a cliché in the circles that dealt with Royal Commissions But what had happened to this Royal Commission? It was the Government who directed what the Commission might and might not consider It was the Government, not the Commission, who decided the considerations that bore on the remuneration of doctors And these considerations boiled down to a specific comparison with other professions He had no doubt that the Royal Commission could compare the incomes of members of various professions But the hours of work differed completely the doctor was at the beck and call of the public at any minute in the twenty four hours The length of the training varied between one profession and another The responsibilities were not comparable But most important of all, these terms of reference had been so drawn up that they limited discussion, they excluded points which were greatly in the doctors' favour, and prevented them from bringing forward their case properly He was sure that that was not the intention of the Government, but that was how it was going to work

The doctors did not expect much good to come out of this Royal Commission Lord Moran himself was concerned that harm did not come from it He was thinking, in particular, of the "merit awards" These awards were brought in at the beginning of the service as an incentive, for it was seen that by going into a service the doctors would lose the competitive stimulus At first the idea met with some suspicion in the profession It was felt that the London medical schools might swallow them all up, and that the consultants in remote parts might be forgotten But there could be no doubt that at the moment the system enjoyed the confidence of the great majority of the consultants, and that they would be most aggrieved if anything happened to these merit awards Would the Royal Commission, he asked go into details of this kind?

CHANGING MINISTERS

But the dispute went deeper and was more fundamental than any question of finance It was a symptom of a good deal of unrest in the service When medicine was nationalised, it was carried over the heads of the doctors by the politicians The minority which supported the National Health Service Act and tried to work for its good had hoped that the doctors would be won over by an enlightened policy It had worked out otherwise It had been heartbreaking to see the bungling and mishandling of the human element Successive administrations had been more concerned with the cost of the service than with putting their minds to making it work While we boasted of our Welfare State, we banished the Ministry of Health from Whitehall and dropped the Minister of Health from the Cabinet In the past seven years, we had had six different Ministers, since Mr Neville Chamberlain's time, we had had sixteen The average life of a minister was twenty months, nine had served for less than a year Lord Moran had the impression that if they had stayed a little longer they might have caught a glimmering of what it was all about

The faults, he admitted, were not all on one side Some of the doctors were uncooperative Many had spent half a lifetime working as their own masters, and they were not likely to be reconciled in their lifetime completely and fully to the different conditions that obtained in a service Nor did it help that in some regions they were treated as employees, instead of being called in as partners in a great enterprise It was from the fringe of this section of disgruntled doctors that appeals came from time to time for a rise in remuneration—appeals which were in themselves just, but which were not always made at the most expedient time From the same section came threats of violent action But many doctors were completely out of sympathy with violent measures of that kind They felt, and Lord Moran shared their feeling, that they must look to public opinion for justice He advised the new Minister to leave his desk and go out into every part of the land, making friends everywhere with the doctors Then, and only then, would the country get some value for the immense sums it was spending on the health service

SUPPORT FROM THE PEERS

Viscount ALEXANDER OF HILLSBOROUGH believed that the service of the medical profession within the N H S had steadily expanded and improved at every point, and that the effect upon the health of the nation had been magnificent In these circumstances, it seemed to him that it was incumbent on the House to urge the Government to amend the terms of reference of the Royal Commission The Commission should not be hamstrung by the tags in the terms of reference which prevented them from looking at the matter with the wide, broad outlook that surely ought to be adopted if they were to deal with the grievance of the profession as it existed today Since the Danckwerts judgment in 1952, the medical profession as a whole had taken no real steps to ask for a steady annual review of their remuneration Only in the past two years had they drawn attention to rising costs, and they had had little sympathetic consideration of those claims

Now that the N H S had been running for almost ten years, Lord AMULREE considered that it would have been timely to set up a committee of inquiry, not because he thought the service fundamentally unsound or wrong but because when a great experiment had been running for ten years it was due to those engaged in it to take stock Instead the Government had set up a Royal Commission only on the payment of doctors That would leave a great deal undone But even under its present terms of reference he hoped that the Commission would deal with methods as well as rates of remuneration He would, for instance, like to see some change in the way of paying general practitioners Unlike the consultants they had no merit awards The only way for the G.P. to make more money was to take on more patients than he could properly cope with

Lord HADEN-GUEST pointed out that though a doctor wanted an adequate income he was not primarily concerned with making money He went into his profession because he wanted to do that work But the amount of money which he could earn in any form of practice or in any medical appointment might be much less than would be earned in ordinary business

Earl JOWITT hoped that the doctors would abandon any idea of what was called a "strike" On the other hand if there was to be arbitration, or its equivalent each side had a right to make its claim and put forward its case At present the doctors thought that the terms of reference did not give the arbitrators enough freedom They might be right or wrong but he felt that they had some reason for thinking so If one compared these terms of reference with those of the Spens Committee one could not but be impressed with the difference between the two If there was to be arbitration, we should start by having the doctors reasonably satisfied with the terms of reference. If they were not, then they were not really being given the benefit of arbitration Where the terms of a remit were found inadequate to embrace the whole dispute they might be enlarged. That should not be done by letters but regularly by enlarging the terms of the remit and putting the whole matter before the arbitration tribunal Lord CONESFORD believed that it was incorrect to describe a Royal Commission as an arbitration tribunal. Again and again the doctors had expressed their willingness that their claim should go to arbitration but that had been refused He could not conceive any lawyer advising the doctors that the terms of reference of this Commission were satisfactory How could they be satisfactory, if the terms on which doctors entered the National Health Service were to be excluded?

GOVERNMENT REPLY

The EARL OF HOME, Secretary of State for Commonwealth Relations and Lord President of the Council, agreed that, within the limits of reason and possibility, justice should be done to the medical profession, because no body of men gave more indispensable service to the people, and none had a greater sense of responsibility The National Health Service was a comparatively novel experiment The State had no inherent virtues as an employer It was the first time it had had to work out a relationship with one of the great skilled professions, and inevitably, it must take time to establish a satisfactory code of relationship and conditions of service The first eight years of the service had run concurrently with a time of intensifying inflation, and the doctors no doubt felt convinced that they had a case for increased remuneration, both actual and in relation to others But the taxpayers also were bearing record levels of taxation and they had an unanswerable case for relief The Government were responsible not only to the doctors but also to the taxpayers

The Spens Committees were set up to investigate the proper remuneration for doctors entering the National Health Service in 1948 But it had seemed to be argued since then that because the Spens Committees based their recommendation for remuneration on 1939 prices, subsequent settlements must always guarantee the doctors against the extra costs brought about by inflation He did not believe that that was really a tenable proposition So long as inflation persisted, it was impossible to insulate one profession against the effects of it or to guarantee that all professions should advance in their remuneration with proportional precision The remedy was to stop inflation, and that required the restraint of wage-earners and salary-earners Till then the best we could do was to try to ensure that no section of wage earners or salary-earners was put at a relative disadvantage to any other section of comparable skill and attainment

The Spens reports were accepted by the Government of the day and were expected to provide a basis for the entry of doctors into the National Health Service What, in the Government's opinion, was needed now, after eight years of experience of the workings of the National Health Service, was to determine the proper place of the medical profession in relation to other skilled professions, and, when that was done, to fix their scale of remuneration They believed that the Royal Commission could be the proper instrument for this It could take into account all the circumstances that were relevant, and one of the factors which was clearly relevant was consideration of the Spens reports If the doctors wished to put before the Royal Commission their interpretation of the Spens reports, there was no reason why the Commission should not listen to and consider their views upon them He had taken the advice of the Minister of Health and he was advised that what he had said fell within the terms of reference given to the Royal Commission

Other criticisms of the Commission included delay, but the Commission had already held a number of sittings and the chairman had every intention that it should act with speed. There had also been a criticism that there were no doctors or dentists on the Commission The Government took the view that on the whole, they would be more valuable as witnesses, and so long as the Commission had competent and able people on it, it was a good body, which would be seen to be impartial. It has also been asked why, if the terms of reference proposed comparison with the remuneration of other professional classes, they did not also include a direction to take into account remuneration in commerce and industry. The Government thought that, had there been a direction to that effect, it would have meant an immensely long inquiry, and there was a great field in industry and commerce in which conditions were not comparable at all He understood that the Royal Commission would normally be concerned with the levels of remuneration and not with the methods, as such Whether they would find it necessary to look at the question of merit awards in order fully to discharge their terms of reference would be for them to decide.

The Government hoped that the interim help which had been given to the profession, followed by a Royal Commission, armed, as they believed, with fair terms of reference, would enable them to move away from the atmosphere of distrust, of accusations of bad faith, of trials of strength and non-coöperation with the Royal Commission and with the health service, because that seemed out of character in a profession recognised everywhere for its sense of responsibility But it was equally true that the community, who were the new employers should not trade on the tradition of patience and good will of the doctors There must be understanding and sympathy on both sides The Commission were already pursuing their task, and he hoped that after they had reported, we should be able to arrive at a permanent settlement which would end for the doctors this rather unhappy chapter in their affairs

Lord Moran remained dissatisfied, for he pointed out that Royal Commissions were strictly bound by their terms of reference It was not the Minister of Health who would advise what those terms were, he had not the power It was for the chairman of the Commission If the Commission decided that this was outside their ambit nothing would happen "I go away," he said, "by the same door by which I came in, with no surety about the awards and nothing whatever on this matter of Spens"

QUESTION TIME

Cost of Prescriptions

Mr Blenkinsop asked the Minister of Health what had been the trend in the cost of prescribing under the National Health Service in January and February, 1957, as compared with previous months—Mr Dennis Vosper replied The average cost per prescription in January was about 5s 6½d This was almost the same as in December, and about 5d higher than in November An accurate figure for February is not yet available, but from a sample it is estimated that the average cost was about 1d more than in January Mr Godfrey Nicholson Is my right hon Friend aware that the medical training of doctors includes absolutely nothing to make them cost conscious? Does he not think that efforts should be made to inculcate in the medical profession some consideration of the cost of prescriptions? Mr Vosper Yes That is why my predecessor decided to set up a committee to examine the whole question of prescribing That committee will, I hope, start work very shortly

Nursing Recruitment

In 1956 20,000 girls began training as nurses or assistant nurses In the same year, 8000 withdrew

Medicine and the Law

Tetanus After Operation

At the inquest on two men who died of tetanus after operations at the North Staffordshire Royal Infirmary, Stoke on-Trent,[1] the jury returned a verdict that they "died from post operational tetanus accidentally contracted in a hospital operating theatre" The jury felt that there should be a thorough investigation as soon as possible,[2] and the coroner said that he understood that there would be inquiries by the Ministry of Health

Dr E M Mackay-Scollay, director of the Public Health Laboratory, Stafford, had given evidence that tetanus spores were found in samples of dust, débris, and wall plaster from the floor of the main theatre corridor, various sites in the annexe, on a naked light bulb, and in a surgeon's gloves No spores were found in any sample of catgut He said "It must be assumed that the process of sterilisation was incomplete The method of sterilising surgeons' gloves might be unreliable" He agreed that it is difficult to destroy tetanus spores, he could not trace the tetanus to any particular source It might have been infected animal hair used in the ceiling plaster in the operating-block A ceiling-light had been removed in the previous month, but its removal had not disturbed the plaster

131 operations had been done in the three main theatres in the week in which the 5 cases of tetanus arose These theatres have not been reopened, nor will they be Because of the tetanus outbreak, the regional board has approved plans for building a new theatre suite, with air-conditioning

We are happy to record that 3 of the 5 patients have now recovered

Obituary

CHARLES ERNEST SCOTT

M B Edn, F R C S.E

Mr Scott, who died on April 3 at the age of 61, was otolaryngologist to nine hospitals in Edinburgh and the Borders, and in all his parish he was recognised pre-eminently as the children's ear, nose, and throat surgeon

He was born at Selkirk, the son of Gideon Scott, and educated at Selkirk High School and Fochabers Academy His medical studies at Edinburgh University were interrupted by the 1914–18 war, during which he served with the Royal Navy, in Scapa Flow, as a surgeon probationer After qualifying in 1921 he held resident appointments at Edinburgh Royal Infirmary before becoming clinical assistant in the ear, nose, and throat department Later he became senior clinical assistant and clinical tutor to the department and in 1926 he took the F R C S E

The following year he received his first senior appointment when he became assistant E N T surgeon to the Royal Hospital for Sick Children In 1929 the hospital opened the first children's ward in the country to receive only E N T cases Mr Scott was given charge of wards in this hospital and in Leith Hospital in 1933 He also had beds at Western General Hospital, later transferred to Eastern General Hospital He was on the staff of the Edinburgh City Hospital for Infectious Diseases and the Princess Margaret Rose Hospital for Crippled Children

His service as secretary to the Scottish Otolaryngological Society from 1933 to 1946 was only broken by his year as president

J F B writes

Charles Scott had to the full the finest qualities of a Borderer—a natural reserve and modesty, a ready wit and a wide range of interests He shared the Borderer's love of rugby and, having played for Edinburgh University, he was a regular and welcome spectator at the seven a sides in his boyhood country He was an expert fisher and a keen curler In his sports cars he travelled widely in Scotland with his cine camera, and his colour films of Scottish scenery were greatly appreciated by his friends and the staffs of his many hospitals to whom they were shown Possibly his greatest hobby was the workshop which he had made in his house, where he turned out many examples of precision engineering He built numerous wireless sets, and constructed his own television set and high fidelity amplifier

Kind, gentle, thoughtful, and conservative he had an unequalled experience of his specialty as it affected children, an experience which could never have been expressed in print, depending as it did on a highly developed clinical judgment His clinical talents were communicated by precept and example to those who worked with him One could never wish for a more kindly or more helpful senior colleague, or one who could more persuasively train one's thoughts within the narrower confines of children's work, and teach the patient approach so necessary in handling the young Tens of thousands of parents have been grateful to him for the care and attention which he gave their children The same kindly manner, the diagnostic skill, and the meticulous operative technique were appreciated by the adults who sought his advice

The death of his wife was a heavy blow, for they were a devoted couple, but he found solace and companionship in his son, who shared so many of his hobbies and interests He faced his own illness with characteristic courage and humour Many friends will miss his counsel and his deep humanity as well as his wide interests which he was ever ready to share

FREDERICK DURAN-JORDA

M D Barcelona

During the Spanish civil war Dr Duran Jorda, a consultant pathologist of Barcelona, organised the blood-transfusion services of the Republican Army to such effect and with such originality that he was invited to advise other European countries on their services In 1939, with the help of the British Red Cross Society he came to this country, and he worked at first as a laboratory technician at Ancoats Hospital, Manchester In 1941, after being admitted to the Medical Register, he was appointed assistant pathologist to the hospital, later becoming pathologist Since 1949 he has been director of the department of pathology at Booth Hall Children's Hospital and Monsall Hospital.

---

[1] See *Lancet* March 16 1957 p 575 March 23, p 634

[2] *Manchester Guardian* April 4

In these posts he was able to continue his studies on the blood, notably on the formation of the red cells His hypothesis that these are secreted by eosinophils was supported by exhaustive investigations, including studies of the blood of horses and camels After he was appointed to Booth Hall Hospital he reported a series of observations on the renal ducts of Bellini, whose interpretation was, like his views on blood-cells, regarded by most other workers as very certainly interesting but less certainly correct As lately as this year, he briefly described (with Mr A McDowall) a method of treating burns by the application of plasma

J T writes

All those who at one time or another of his hazardous life came into contact with Duran-Jorda will remember, as perhaps the most outstanding characteristic of his remarkable personality, his vitality which could not but impress by its almost torrential flow Even in the last phase of his illness—which an irony of Fate had made him, the creator of large scale blood-transfusion, diagnose in his own blood—his unabated energy did not desert him until the very end The name of Duran Jorda will be for ever linked with the organisation of the first blood bank for transfusion in war, a unique achievement which heralded the enormous revolution in life saving procedures which made the two world wars differ so much from each other As a surgeon in charge of a large hospital I witnessed the miracle which under his inspiration took place in Catalonia at the time of the Spanish war Severely wounded soldiers could be operated on with success in Barcelona eight or ten hours after the infliction of the injury, having been transfused at the front line and transported scores of miles while the pressurised citrated blood transfusion kept them alive By the end of the war over 25,000 donors had been organised by Duran-Jorda, and the experience then gathered was of inestimable benefit to us all when later, at the invitation of the British Red Cross, he came to this country to make it his home

An idealistic, patriotic, extroverted Catalan, he found himself surrounded here by a people whose values in life were very near to the ideal for which he had fought in Spain He told me on several occasions that in Lancashire he had found an industrial society loving freedom and music, two characteristics also of the Catalans A man of an extraordinarily impulsive nature, he was a meticulous recorder of observations and an accurate reviewer, and even critic, of his own achievements He was a happy man by nature and one could see him always surrounded either by his family or by his *microscopes*

It seems to me certain that time will enhance the value of most of his contributions His method for early treatment of burns and scalds merits more attention than that it has yet received, and several of his other works have brought him international recognition Above all he had the tacit recognition of all those who owe their life to a readily available blood-transfusion This was the highest prize for the simple and modest pathologist whose enthusiasm and organising ability contributed so much to the well being of so many people I hope that for this his name will not be forgotten

As an old friend who came to this country at the same time as he I express the sentiments of thousands in England—as in Catalonia—in waving a cordial farewell to a warrior whose only fear was to harm

Dr Duran-Jorda leaves a widow with two children He died on March 30 at the age of 51

Appointments

BETHELL, M F, M D Camb, D P M consultant psychiatrist and deputy medical superintendent, Tone Vale Hospital, near Taunton

BURROWS, H P, M B Lond, D I H district M O H, parts of Holland, Lincolnshire

MOORE, F W, M C, M B Brist, M R C P E, D M R D, D P H consultant radiologist, Bath clinical area

O DONNELL, [illegible], M CH, N U I, F R C S I county surgeon, Tipperary (N R), Ireland

ZEITLYN, B B, M D Lond, D P M part time consultant psychiatrist, Addenbrooke's and Fulbourn Hospitals, Cambridge

Notes and News

TOWARDS PREVENTING SUICIDE

A "psychotherapeutic" club has been provided by the public health department in Salford for the past few years, where mildly depressed and anxious patients may attend each afternoon from Monday to Friday The staff believe that several suicides have been prevented, and some withdrawn patients have made a striking recovery

Two afternoons each week are devoted to occupational therapy Patients are encouraged to bring handwork from home for instruction, and many have learned to use a sewing-machine One afternoon is devoted to drama therapy, play-reading, and acting as a group, and another afternoon to art therapy, free drawing, and painting Part of each afternoon is spent in music therapy, but that is one of the less popular subjects A psychiatrist attends weekly and gives private consultations and sometimes group therapy Half an hour of games has recently been introduced A mental-health social worker attends regularly Both the psychiatrist and the social worker have "time to listen" to the patients' anxieties, and the patients feel at the club there is someone who knows them, cares for them, and understands their difficulties

Although the club is a small one (at present about a dozen attend daily), it illustrates how much help can be given in this way Such clubs are comparatively simple and inexpensive to run, and in contrast to many of the schemes that have been described, they are in the community—to which the patient will have to return and in which he must learn to live—and not in hospital premises which are in several senses remote from the patient s home and social environment

A FILM FOR DIABETIC PATIENTS

A NEW film, *The Diabetic Diet* (16 mm, sound, black-and-white, 14 minutes) was lately completed with the coöperation of the medical advisory committee of the British Diabetic Association

In the opening sequence an analogy is drawn between a car engine and the human body, showing that fuel consumption in each case is related to energy expenditure Carbohydrates proteins and fats are described briefly and the storage of glycogen in the liver and its conversion to glucose with the aid of insulin are shown on an animated diagram Insulin deficiency can be made up by *injection* but the *dosage* must be accurately determined by a doctor The balance is then maintained by the patient having his meals at the right time and checking his urine regularly Reference *is made to the Diabetic Cookery Book* particularly to the section describing how, by interchanging foods of equivalent carbohydrate values, appetising meals may be prepared without altering the total allowed by the diet

The first part of the film, explaining the theory of diabetes, is valuable for patients and their relatives who prepare their meals But in the second part—which adds little to the information already available in the *Diabetic Cookery Book*—the scenes of a patient eating become monotonous, and shots of the sponsors' products are unduly extended The animated sequences are clear but rather long, and in places *the commentary is not well related to the action*

Copies of the film may be obtained, free of charge, from the Gaumont British Film Library, Aintree Road, Perivale, Greenford, Middlesex

---

University of Cambridge

On March 23, the degree of M CHIR was conferred on *C H Talbot*

On June 13 the honorary degree of SC D will be conferred on Sir Geoffrey Jefferson, F R S

Royal College of Physicians of London

Dr F P Lee Lander will deliver the Mitchell lecture on Tuesday, May 28 at 5 P M at the college, Pall Mall East, S W 1 He will speak on rest and pulmonary tuberculosis

Royal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty held on April 1 with Prof Stanley Alstead, the president, in the chair, the *following* were admitted fellows of faculty qua physician

Goniamalimigie Herbert Allan Aponso Ashoke Kumar Dutta, Shanpur Janardhana G P McNicol

Heberden Society

A Heberden round will be held at the rheumatic unit of the Northern General Hospital Edinburgh, on Thursday May 16, at 11 A M

Scottish Medical Practices Committee

Dr John Baldwin, general practitioner of Penicuik, has been appointed chairman of this committee in succession to Dr A F Wilkie Millar

Institute of Diseases of the Chest, London

Clinical demonstrations, arranged by Dr F H Young, will be held at this institute (in the grounds of the Brompton Hospital, Fulham Road, S W 3) on Fridays, at 5 P M, from April 26 to July 5

Glasgow Medical Exhibition

Prof Stanley Alstead will open this exhibition at 11 30 A M on Monday, April 29, at the McLellan Galleries, Sauchiehall Street, Glasgow It will be open daily from 11 A M to 6 30 P M (8 P M on April 30) till May 3

South West Metropolitan Regional Hospital Board

The following have been awarded prizes in the board's 1956 competition

Consultants and S H M O s—Mr E H J Smyth Mr J H Mulvany, Dr A T Huston

Senior registrars, registrars, and J H M O s—Mr R A Denham, Dr J L Crammer Dr R S Jones

Senior house officers and house officers—Dr Ann Mullins

Notice of entry for this year's competition (with proposed subject) should be sent to the board's senior administrative medical officer (Gen /OST), 11A, Portland Place, London, W 1, by Sept 30, and reports must reach him not later than Dec 31

Broadcasts on Mental Health

The first of six weekly broadcasts on this subject is to be given on the Home Service on Wednesday, April 17 The programmes will include recordings made by patients, doctors, nurses, and welfare workers, and they will deal with the development of the child's mind, alcoholism, the rôle of the Churches in combating mental illness, and the problem of neuroses and everyday relations After the series, on Tuesday, June 4, at 7 45 P M, a panel of specialists will try to answer questions or criticisms arising from the programmes Listeners are invited to send their comments to Mental Health, Broadcasting House, Queen Margaret Drive, Glasgow, W 2

The B B C 's leaflet, *Mind Out of Balance*, published when this project was first announced, is still available and may be obtained by sending a stamped, addressed envelope (2*d*) to B B C Publications (Mental Health), 35, Marylebone High Street, London, W 1

British Association of Physical Medicine

Sir Cecil Wakeley, at the annual dinner held at the Royal College of Surgeons on April 5, said that from the first world war he had had reason to be grateful to those who practise physical medicine There was no branch of surgery that did not benefit from the work of the association The orthopædic surgeon relied on it, and " where would the thoracic surgeon or the geriatric surgeon be without your help ? " Even in the mundane treatment of varicose veins it was a necessity ' we strip the veins but you get rid of the ulcers ! " Dr P Bauwens, the president, recalled that since he took his first very junior post as a medical electrologist 30 years ago he had witnessed the birth, gestation, and formative years of physical medicine It defied definition yet had distinctive features, and he likened it to a painting with varying motifs which in course of time had come to form a well balanced pattern This picture, to which each generation added its contribution, he saw as a panel in a triptych whose other parts were medicine and surgery, and the themes of the three panels were sometimes different but often repeated and mutually complementary He hoped that, despite the continuous process of overpainting, the balance of the physical medicine panel and its main features would remain intact Group Captain C J S O'Malley, proposing The Guests, said that though young, the British Association of Physical Medicine, formed in 1943, was closely linked with old societies formed for mutual help, protection, good fellowship, and the protection of their crafts His kindly speech drew a response from Mr J C Butterwick, prime warden of the Goldsmiths' Company, which has been responsible for the presidential gold badge of the association, presented by the late Lord Horder He quoted Dryden's statement " the wise for cure on exercise depend,' and gave some account of his company s successful efforts in the past 8–9 years in training occupational therapists to teach the disabled how to make simple jewellery

Chronic Bronchitis

The National Association for the Prevention of Tuberculosis is holding a symposium on this subject on Wednesday, May 29, at 3 30 P M in the Clinical Science Building, York Place, Manchester, 13 Prof Fraser Brockington will be in the chair and the other speakers are to be Dr Lynne Reid, Dr Charles Fletcher, Dr D D Reid, Dr Thomas Lodge, Dr J L Burn, Mr Keith Roberts, Dr John Pemberton, and Dr William Robinson Further particulars may be had from the N A P T, Tavistock House North, London, W C 1

Society of Chiropodists

Speaking at the annual dinner in London on April 4, Sir Zachary Cope said that a book on the Feet, dated 1818, called on the Royal College of Surgeons to institute a sub diploma for chiropodists, but the first society was not formed until 40 years ago, and the union resulting in the now famous Society of Chiropodists took place only 10 years ago Chiropodists had been fortunate in having such good leaders, and he referred with pleasure to an award given earlier in the day to Mr J H Hanby Responding, Mr J R Hall, the president, said that in the past 8 or 10 years Sir Zachary had done more for medical auxiliaries " than anyone else we know of," and the conclusions of the Cope report were the first real basic recommendations ever put before the Ministry of Health and the public When agreement could not be reached, the protests of the Royal Colleges and the British Medical Association led to the setting up of a working party, and those who had gone in as " medical auxiliaries " came out, in the draft Bill, as " professions supplementary to medicine " A supplement was something that supplied a deficiency, and these professions supplied a deficiency in the Greater Medical Profession. Mr Hall hoped it would not be long before the Bill was passed and chiropodists were recognised with the new onus upon them they would try to maintain the same high principles as hitherto, recognising both in their private and in their professional life all that is involved by professional status Mr D Neale, proposing The Guests, thought that an empty chair might have been put at the table to symbolise an absent guest—the patient, " to whom we are all dedicated " In his reply Sir Heneage Ogilvie said he had been a guest in every continent except Antarctica, but his Swahili was inadequate and his English not as good as it should be Though he had often responded before, he still suffered from what those notable medical auxiliaries, the psychiatrists, would call the *Daniel complex* *Having* reviewed the development of numerous surgical specialties, culminating in the surgical biochemists whose talk is all of corticosteroids and milk equivalents, he expressed his belief that the really important people in the medical profession are the general practitioners —" because they don't think themselves important "

Baillière, Tindall, & Cox Ltd, have taken over the publication of *Public Health*, the official journal of the *Society of Medical Officers* of Health, for the society The journal has been redesigned and will first appear in its new format this month

SOME PRINCIPLES OF PSYCHOTHERAPY IN GENERAL PRACTICE*

J. A. HARRINGTON
M.D. Camb., D.P.H., D.P.M.
CONSULTANT PSYCHIATRIST, ALL SAINTS' HOSPITAL AND UFFCULME CLINIC, BIRMINGHAM

SOME psychiatrists think that nothing is achieved by giving lectures or short courses on psychotherapy. I do not share this view. Psychotherapy is neither a purely intuitive art, which depends entirely on the personality of the doctor, nor something so esoteric that it can be undertaken only by trained psycho-analysts. Though long and specialised training is necessary for some types of analytic psychotherapy, many useful techniques can be acquired and used in general practice.

The bulk of straightforward psychotherapy is already done in general practice, and this is likely to continue to the betterment of general practice and psychiatry. Not every neurotic or "functional" disorder needs specialist attention. Many patients are frightened by being sent to a psychiatrist, and some refuse clinic appointments for this reason. Hence the general practitioner has to practise psychotherapy, in one form or another, whether he likes it or not. The problem is to make this form of treatment more effective and widely applied.

Psychotherapy remains an art, and has so far eluded study by accepted scientific methods; it contains no absolute truths. Nevertheless there is a body of principles that can be learnt and applied to its practice.

Before embarking on some of these principles I want to explode a few of the *misconceptions* that surround it. The first is that this treatment is too time consuming to be undertaken in general practice. This is true of analytical psychotherapy, but not of the many simpler methods. The second is the fable of the buried treasure—the idea fostered by films and books that a single traumatic episode buried in the patient's past caused the condition, and if the doctor can dig it up all will be well. One does not have to practise psychiatry and psychotherapy very long to know that this is true of very few patients. The third misconception is that an extensive knowledge of psychodynamics is needed. In point of fact much effective psychotherapy is done without recourse to the unconscious mind and without speculations about repressed conflicts and motivations. Indeed, too much sophistication in mental mechanisms, and too little common sense, may be a positive hindrance to success.

What is Psychotherapy?

Broadly speaking, any form of treatment designed to produce a response by its mental rather than its physical effects is psychotherapy. Such treatment falls into two groups. The first (which has been aptly called bedside manners or "prescribing the doctor") uses suggestion, persuasion, re-education, reassurance, and support. It includes managing the patient's problems and bringing about changes in circumstances which are noxious to him. This kind of psychotherapy is most suited to general practice.

The second group are the so-called deeper forms of psychotherapy, which often aim at uncovering psychological conflicts of which the patient is unaware and relating them to his problems. This group includes such special techniques as hypnosis, abreaction, and psycho-analysis, which are best left to those with special knowledge and experience.

History and Examination

History-taking

Unless the patient is already known to the doctor, history-taking constitutes the first interview, and first impressions are very important for both patient and doctor. Not infrequently the taking of a fairly detailed life-history is all that is needed to get the patient better. The opportunity to ventilate his problems with a sympathetic listener may previously have been denied him.

The important thing in history-taking is the *attitude of the doctor*. The key to a successful history is to be able to convey to the patient that one has plenty of time and is sympathetic and interested in his problem. One can learn to convey this impression to the patient even if one is short of time and not particularly interested. The technique I adopt is to allow the patient several minutes to say anything he wants, unprompted and uninterrupted, before proceeding to any special line of inquiry. Much of what the patient says may seem trivial and irrelevant but he must get the feeling that he has had a chance to say what he wants.

Besides the maxim "It's not what you ask but how you ask it," certain other points deserve mention. We all face the problem of being selectively deaf in history-taking: we hear only the things we want to hear. To approach every neurotic with a fixed idea that the problem must be sexual is as naïve as to suppose it never is.

One should avoid direct reassurance too early in the history even if the patient asks for it. Too quick reassurance is as unconvincing as that of the motor mechanic who says there is nothing wrong with the engine without so much as taking a look under the bonnet.

One can often see the key to the situation by watching the patient's expression of emotion during the examination. He may tremble with anxiety, burst into tears, or flush with anger when talking about people or situations which affect him closely. Likewise silence or evasion of a particular topic may be significant. It is unwise to press questions if the patient does not seem ready to answer them. Some neurotics have great difficulty in talking about their troubles; so the doctor should not be surprised or disappointed if the real problem does not emerge in the history. With tact and patience it will emerge later when the patient feels secure with the doctor. Be suspicious of the patient who produces intimate material on a plate at the first meeting—he may be near psychotic.

I have always found it a good plan to round off the history by asking the patient what he himself thinks is the trouble and how he thinks he may be helped to get better.

Physical Examination

The examination can be made an important adjunct to psychotherapy. The ideal time and place to reassure a patient is during and immediately after physical examination. If allowed to do so, a patient while being examined will often reveal information that he previously forgot or feared to mention.

An examination which is excessive is as dangerous as one which is cursory. An intelligent patient is not likely to be convinced there is nothing physically wrong if one only looks at the tongue and feels the pulse; but where neurosis is suspected, the greater danger is of too protracted an examination, too many special investigations, and indecisiveness about the results. It is highly important to get the physical side of the case cleared up right at the outset, and not to reopen it without definite indications: if one later yields to the patient's request for further physical investigation, his confidence is bound

Q

to be shaken. It is equally important to tell the anxious patient in very definite and simple terms the results of the physical examination.

Quite a number of emotional illnesses are precipitated or perpetuated by the doctor quite unwittingly. We are all guilty of contributing at times to these iatrogenic neuroses. Every psychiatrist sees patients who have been in the hands of three or four different specialists, all of whom are said to have told the patient something different. Such patients are hard to treat because they have lost faith.

If special investigations are pursued for several months the neurotic patient is bound to be influenced unfavourably. Moreover, laboratory studies are fallible and there is the oft quoted risk of placing too much weight on minor variations. The sooner one has the courage of one's conviction that there is nothing physically wrong, and tells the patient so, the better. Neurotics are very keen to have a definite cause for their symptoms and will fasten like leeches on to "fibrositis" or the like as the cause of their troubles. Once they are fixed in this sort of belief it is much harder to get them well.

If the patient is determined to have some special investigation, it is probably best to get it over and done with straight away—but on the understanding that it is to settle the issue and not be the prelude to a series of further tests. Our medical training makes us rightly afraid of missing hidden physical disease, but it makes us insufficiently aware of the danger of creating invalids by doubts and indecisiveness.

I must emphasise, too, that emotional disorders should not be diagnosed by the exclusion of a suspected physical cause. Their diagnosis must be based on the positive finding of an emotional disturbance in the patient.

The Therapeutic Interview

In most forms of psychotherapy an interview with the patient is the main vehicle of treatment. These methods have the common factor that they depend almost entirely on communication between patient and doctor. This communication may be spoken, or it may be implied by means of expression and gesture. There are no rigid rules, but some general principles of the therapeutic interview deserve consideration.

Number, frequency, and duration of interviews.—Many emotionally sick people can be adequately treated in half a dozen interviews or less. Some need many more, but I doubt the practicability of long-term psychotherapy (except of supportive type) in general practice. Weekly interviews are better than monthly, for long intervals make the treatment too diffuse to be effective. Forty minutes is long enough for most patients, though many will do very well with twenty. Some anxious patients cannot tolerate talking to the doctor for more than ten minutes or so.

Situation and flexibility.—Psychotherapy is traditionally depicted with the patient lying on a couch. Though this is regarded as essential for psycho-analysis, the face-to-face interview is better for less intensive treatment. Flexibility is a very important principle of psychotherapy, but it is not identical with vagueness. The standard method must be tailored to individual needs. The same technique will not fit both the managing director and the semi-literate man who sweeps the floor in his factory.

Objectives and errors.—Before embarking on treatment it is important to decide the objectives for each case; they should be kept in mind throughout treatment. The aim may be to get the patient symptom-free, to give him some relief, to get him back to work, to save his marriage, or to keep him going until circumstances take a turn for the better. The aims should be realistic. Many doctors get discouraged about their therapeutic ability by putting the sights too high. Our influence on the patient is considerable but not infinite.

Though there are plenty of mistakes to be made in psychotherapy, one should not be put off by fear of making them. Many of the errors can be corrected. Psychotherapy is not as dangerous as some make out. A common mistake is to use such clichés as "Don't worry," "Snap out of it," and "Pull yourself together." There is nothing a neurotic resents more than being told to pull himself together; he has been told this many times and has told it to himself before he saw the doctor. In most cases such admonitions convince the patient that the doctor does not understand him. Nor should one tell him that his troubles are purely imaginary; symptoms are always real to the patient.

Avoid giving advice unless you are confident your counsel is correct and will do no harm. This applies to patients who ask for advice as well as those who do not. It is generally a mistake to tell a patient to marry, to have a baby, or to change a job—in vague expectation that this is the solution of his difficulties. The new responsibilities often create additional problems. If the patient presses for advice, it is best to discuss the matter fully and help him to *reach his own decision*. If you give concrete advice be prepared to have it thrown back at you later.

Avoid prejudging the patient and his problems. Though one should try to feel with the patient, do not become so identified with his problems that you make him do what you would have done in his particular circumstances. Patients are individuals with their own aims and objects. The Pygmalion approach is almost always mistaken; the therapeutic subject is not clay to be moulded according to the doctor's ideals.

Timing, Minimal Activity, and Focus

The factors causing a patient's symptoms may be obvious after one interview; but, though very tempting, it is unwise to tell the patient all you know. Premature interpretation of the situation, even if it is correct, will be rejected. Unpleasant truths take time to be accepted. Correct timing here is as important as in glass blowing, where attempts to mould the material before it is at the right temperature may fracture it or cause it to run. The patient should be led by inference into seeing the situation for himself without being told directly. Self-made interpretations are more likely to be accepted than those made by others.

Patients will rarely benefit from a lecture or sermon. The aim should be to get the patient to do the talking. The less active the doctor the better. Keeping one's mouth shut is probably the hardest psychotherapeutic lesson to learn. One should not be afraid of saying little or nothing, or of pauses and silences. If we start to talk as soon as the patient dries up, the conversation will probably remain on a very superficial level. Half the art of psychotherapy is to be a good listener. Conversational grunts, and exclamations such as "uh huh" and "humm" which lack an air of finality, help to keep the patient talking without interrupting him. One's facial expression, intonation, and gestures can all help to keep the conversation going. If the patient comes to a halt, one can often get him talking again by repeating one of the last phrases or words he spoke. If he dries up completely one can discuss why he has difficulty in talking.

Some patients are evasive and become more so when discussing their real problems. They tend to be repetitive and to circle round and round the topic of their symptoms. By showing lack of interest when they talk of symptoms, and interest when they start to talk of something else, one can get them to focus on matters of importance. In short-term therapy it is quite legitimate to select important topics and ask the patient to talk about them, but leading questions, and those with the answer yes or no, should be avoided.

It may be a good plan to start treatment by a brief explanation of its aims, thus preventing the patient from expecting too much of the doctor and too little of himself. The patient must see the treatment as a cooperative effort.

Some patients have a fixed idea about the way in which they can be helped, and one can prevent blunders by finding out about this. They may have great faith in some particular nostrum, and if so one should be aware of it. It may, for instance, be good psychotherapy to prescribe a placebo. Many patients, particularly from the lower social strata, have so accepted the tradition of the "bottle of medicine" that if one resolutely refuses to prescribe any medicine with psychotherapy they will not come again. A small prescription may ensure the initial cooperation necessary for psychotherapy. This does not mean that the doctor should always heed a patient's wishes or become a pawn for him to manipulate. The doctor should remain in discreet control of the treatment situation throughout.

The Doctor-patient Relationship

Most psychiatrists agree about the fundamental importance of the doctor-patient relationship in psychotherapy of all types. This relationship can be defined as the mutual interaction between the personalities of the patient and of the doctor that pervades all treatment. The relationship is not one-sided and shows a large number of variations.

For convenience it is easier to consider the two sides of the relationship separately, though in reality they are indivisible.

The Patient's Attitude to the Doctor

To the sick person seeking help, the doctor is not just another person. Even today the patient not only thinks of him as an accomplished expert in medicine and accords him his traditional and cultural rôle; he also sees him as a symbolic figure. Many emotionally sick people do not go to a doctor for help. Those who decide to seek help from medical sources differ in their attitude to the doctor from those who go elsewhere or nowhere at all.

Patients may exhibit positive or negative feelings of great intensity towards the doctor. Such feelings may be of awe, distrust, anxiety, warmth, hostility, or subservience. The type of reaction a patient shows to the doctor is determined more by the patient's personality and previous experience than the doctor's.

Some examples may help to explain. At one end of the scale are the patients with a really positive relationship with the doctor. They often come along with their minds already made up that you are a good doctor with almost magical powers to help them. They sing the doctor's praises even before anything has been done for them. They take his advice and treatment without a murmur. They even, to please him, say they are better and are profusely grateful for the smallest attention. Such patients are good for the doctor's vanity and feeling of omnipotence; but they do not always persist in this attitude.

At the other end of the scale are the patients with strongly negative feelings about the doctor. They may be openly hostile, truculent, and aggressive, or more subtly they turn up late for appointments, fail to take the treatment prescribed, and do not discuss their problems openly. They are bad for the doctor's vanity and tax his patience to the utmost. The surprising thing is that they often continue to seek the doctor's help.

Between these two extremes we find the bulk of patients, who show mixed positive and negative feeling towards the doctor. Such patients' attitudes often fluctuate.

It is of fundamental importance to recognise that the patient's attitudes to the doctor are nearly always predetermined and *not personal* in any way. Some people may tend to repeat attitudes towards the doctor that have been laid down by previous life experience. In particular they tend to re-enact their childhood relationships with figures of authority such as parents and teachers.

The Doctor's Attitude to the Patient

An understanding of the doctor's part in the relationship is as vital as it is difficult. It is bound to be individual for each doctor and involves a certain amount of soul-searching and recognition of his own outlook and prejudice. Unfortunately, many a doctor cannot tolerate certain shortcomings in his patients—to the serious detriment of his ability to help them. Some doctors cannot tolerate stupidity; others cannot take the patient who is surly and hostile or one who is coy and flirtatious. Certain attitudes in our patients threaten us or annoy us, and we should recognise this. Each of us has his own emotional blind spots, and I do not think we can be all-round psychotherapists unless we are aware of these and how they affect our handling of patients.

It is relatively easy to be a good psychotherapist with certain types of patient suited to our own make-up; the difficulty is to be able to help more than an isolated group of emotionally sick people. A doctor who can learn to tolerate his patient's emotions, in the same way as he learned to tolerate pathological specimens without disgust, has gone a long way towards being an effective therapist.

If we are hostile and annoyed with our patients we cannot get their confidence and cooperation; through lack of empathy the therapeutic relationship does not develop. Doctors who regard all neurotic patients as weak and spineless are not likely to help them.

We all tend to develop defences against our patients, some open and some more hidden. We can of course dub them straight away as "another damn neurotic," or show our dislike more subtly by sending them at once to a specialist for protracted investigation, or abroad for a long holiday. Our letters about the patient often express our feelings well; the adjectives used often tell more of the doctor's feeling than the patient's condition.

Learning psychotherapy does not mean learning a new series of catch phrases; but the technique does involve an awareness of the importance of our own response to the patient and how this influences our ability to deal with his psychological problems.

Finally, I would emphasise again the importance of first impressions. If the doctor is sympathetically warm and accepting at the outset, he can build up the good relationship with the patient which is so important. If, later, the patient has to be dealt with in a more firm and positive manner, it can be done on the basis of the patient's confidence in the doctor and in a way he can more readily accept.

"A celebrated authority on Canon law and mediæval Universities, Dr Hastings Rashdall, was one of those who could ride but not understand a bicycle. One day, for example, having had a puncture in his front tyre, he was found vigorously pumping up the back one; when a passer-by pointed this out to him he remarked 'What? Do they not communicate?' I sometimes wonder whether, in our present-day eagerness to 'put people in the picture,' we do not behave rather like Dr Rashdall, strenuously pumping in information at one end of a firm in the hopeful expectation that it will find its way to the other. Perhaps we too ride but cannot understand."—T. M. HIGHAM, *Occupational Psychology*, January 1957, p. 1.

INTERMITTENT ALDOSTERONISM IN PERIODIC PARALYSIS

DEPENDENCE OF ATTACKS ON RETENTION OF SODIUM, AND FAILURE TO INDUCE ATTACKS BY RESTRICTION OF DIETARY SODIUM*

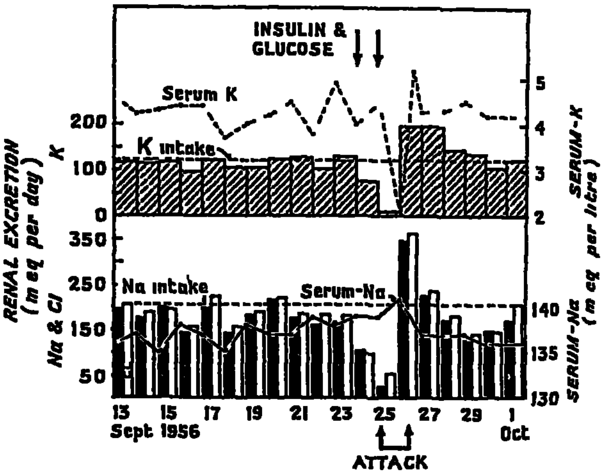
From the Metabolism Research Unit of the Department of Endocrinology and Metabolism, University of Michigan Medical School, Ann Arbor, Michigan

WE have reported that spontaneous attacks of periodic paralysis are preceded by large increases of urinary aldosterone and by intense retention of sodium (Conn et al 1956) This is followed shortly by sequestration of potassium within the body, both serum and urinary potassium falling abruptly and intensely Serum sodium often rises to abnormally high values as serum-potassium reaches its lowest ones As the attack subsides a great diuresis of sodium occurs together with a less intense increase of urinary potassium Serum-sodium and serum-potassium return to normal together By this time urinary aldosterone has returned to base line values

We have explored further the rôle of retention of sodium in setting off potassium sequestration—i e, acute hypokalæmia and hypokaluria Two young men with the familial type of periodic paralysis were the subjects of this study One of them, living in our laboratory, submitted cheerfully to 11 months of a rigid metabolic balance regime The other was studied for 30 days to test in a different person the applicability of the metabolic principles discovered in the first one The subjects are not related

The aim of this short communication is to disseminate quickly information which is of immediate practical value to patients with this disorder Extensive data will be published later At this time we wish merely to outline some of our results and conclusions



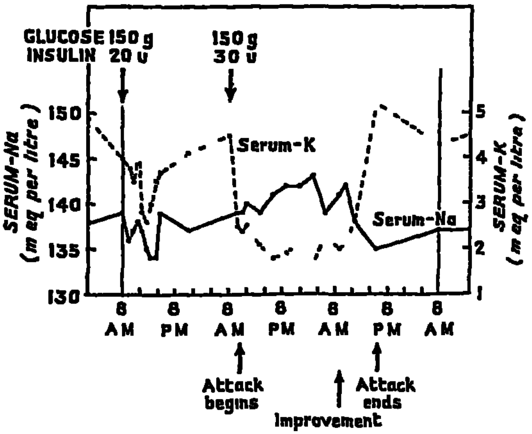


Fig 2—Changes in electrolyte metabolism during episode of periodic paralysis induced by administration of glucose and insulin

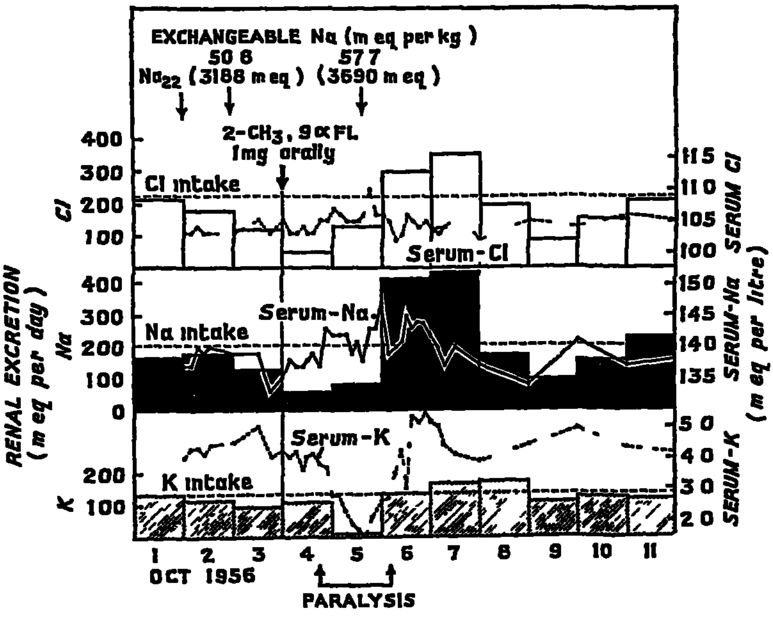

Fig 1—Induction of episode of periodic paralysis by 2 methyl 9-α-fluorohydrocortisone and high sodium intake

Method

Two levels of sodium intake were used—8 and 208 m eq per day The composition of the daily ration was otherwise the same, the high sodium régime differing from the low by addition of sodium chloride to the basic diet Chloride ion, the only other variable, was 27 m eq per day on the low, and 229 m eq per day on the high, sodium ration Potassium intake was constant at 132 m eq per day

Results

Under both of these dietary conditions a series of identical experiments were carried out, each designed to induce an episode of periodic paralysis The following facts were disclosed

(1) When the diet contained the larger quantity of sodium the administration of glucose and insulin, or of 2 methyl 9 α fluorohydrocortisone (an extremely potent mineralocorticoid) produced complete (from the neck down) and prolonged (24–48 hours) paralysis (figs 1 and 2)

(2) When glucose and insulin induce an episode of periodic paralysis the great

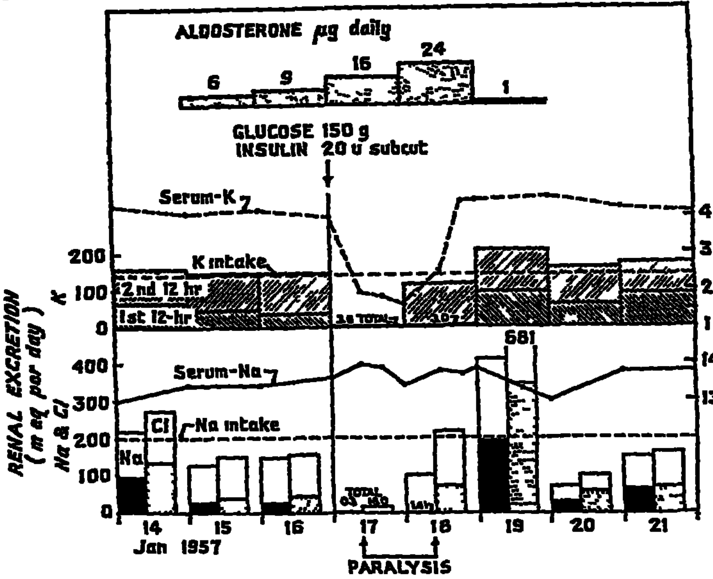

Fig 3—Changes in electrolyte metabolism and urinary excretion of aldosterone during episode of paralysis induced by glucose and insulin. Lower part of histogram first 12 hours, upper part, second 12 hours. Aldosterone estimated by method of Neher and Wettstein (1956).

retention of sodium which precedes the actual attack is accompanied by a sharp rise of urinary aldosterone (fig 3). During the intense diuresis of sodium which follows an attack urinary aldosterone falls below normal. By what means increased utilisation of carbohydrate produces increased secretion of aldosterone in this disease is now under investigation.

(3) In all of these paralytic episodes urinary and serum K fell sharply but the sequestration of K was always preceded and then accompanied by intense retention of sodium.

(4) The very earliest return of muscle function is related temporally to increasing amounts of urinary sodium, and in some attacks it can be demonstrated that serum potassium is still near its minimal value at the time that the ability to move muscles is returning. This is then followed by a rapid increase of urinary and serum potassium.

(5) Total body exchangeable sodium (Na^{22}) was found to be elevated before induction of attacks and this increased considerably during induction of an attack (fig 1).

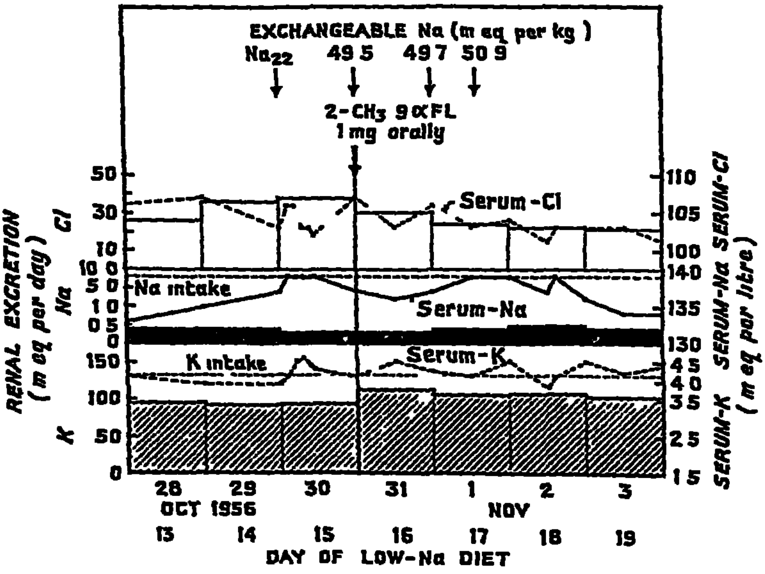

Fig 4—Data indicating failure of 2 methyl 9-α fluorohydrocortisone to induce attack when sodium retention is prevented by low-sodium diet.

(6) When retention of sodium was prevented by provision of the diet very low in sodium, *attacks of paralysis could not be produced* by the procedures which had provoked the severe ones previously mentioned, and sequestration of potassium did not occur (fig 4). This has been demonstrated in both of our cases of periodic paralysis.

(7) As in normal individuals, these subjects when taking the low sodium diet exhibited persistently raised levels of urinary aldosterone, yet there were no attacks. Thus, the sudden sequestration of potassium which accompanies an attack of periodic paralysis is not due per se to the presence of aldosterone. Sodium must be available and must be retained in the body before potassium begins to move to its site or sites of sequestration.

(8) Whereas 2 methyl-9 α-fluorohydrocortisone produced prolonged retention of sodium and diuresis of potassium in normal men (fig 5), it produced sodium retention followed by sequestration of potassium in both patients with periodic paralysis (fig 1). This would appear to rule out the possibility of production of an abnormal potassium retaining adrenal steroid in this disease. Instead it appears that when a sodium retaining corticoid is actively causing sodium retention in periodic paralysis the potassium response is a paradoxical one. This conclusion is strengthened by the fact that we have clearly identified as aldosterone the urinary sodium retaining corticoid found in excess in this disorder.

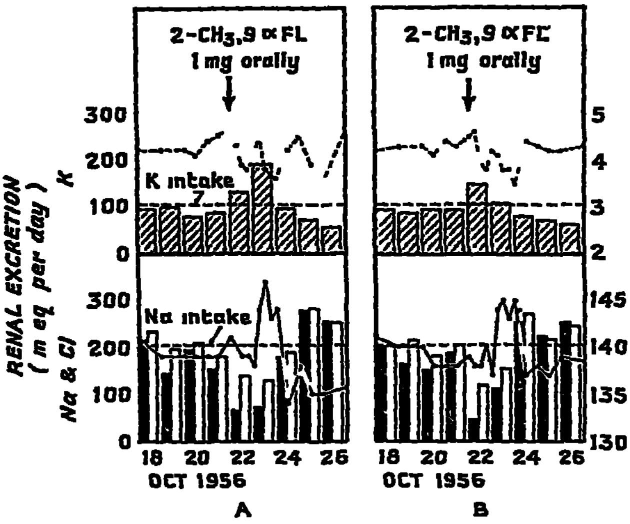

Fig 5—Effects of 2 methyl 9-α fluorohydrocortisone on electrolyte metabolism in two healthy young men aged 21 (A) and 19 (B).

(9) Skeletal muscle obtained during the period of high sodium intake contains much too much sodium and a normal or slightly subnormal concentration of potassium (see accompanying table). Microscopically, the lesion characteristic of this disease is observed—namely, numerous large and small glistening vacuoles within muscle fibres. The vacuoles do not stain as fat or glycogen (fig 6).

(10) In skeletal muscle obtained after 44 days on the low sodium diet this vacuolar change in the muscle fibres has disappeared (fig 6b). The accompanying table shows the values for concentration of Na and K in muscle at this time.

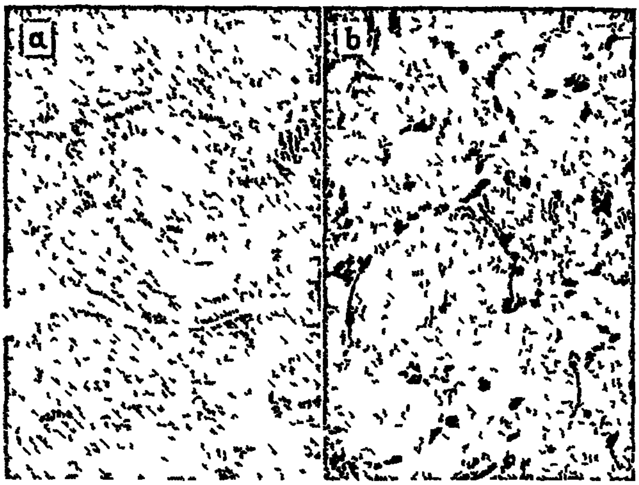

Fig 6—Skeletal muscle from patient with periodic paralysis (a) during high sodium intake, showing vacuoles (b) during low sodium intake, showing no vacuoles

Discussion

The dramatic decrease in the level of serum potassium at the beginning of a paralytic episode in the "familial type" of periodic paralysis has resulted in extensive studies of potassium metabolism in this disease Current therapy consists in administration of potassium salts daily by mouth as prophylaxis, and of potassium chloride intravenously for established attacks We are impressed with the facts that, although an incipient attack can be aborted or a severe one sometimes ended by administration of potassium, they still occur even when 10–12 g of potassium chloride is ingested daily

Studies of sodium metabolism in this disease are meagre In two studies sodium balance was found to be positive before and negative after the attack (Ferrebee et al 1940, Danowski et al 1948), but the significance of this finding was not appreciated It is clear from the present data that the sudden and profound sequestration of potassium is always preceded by an intense positive balance for sodium In normal individuals on very low levels of dietary sodium, urinary excretion of potassium is not increased by administration of 2 methyl-9-α fluorohydrocortisone (J W Conn, unpublished) Thus, it appears that even in normal people the effects of mineralocorticoids upon potassium metabolism are secondary to retention of the sodium ion

With respect to the *clinical* entity of periodic paralysis we call attention to several well-recognised discrepancies which make it difficult to correlate attacks of paralysis solely with an abnormality of potassium metabolism

(1) Attacks of total paralysis may occur at levels of serum potassium which when found in other conditions are not low enough to result in muscular paralysis (Darrow 1946, Danowski et al 1949, Elkinton et al 1951)

(2) The severity of different attacks in the same individual is not correlated closely with the degree of hypokalæmia

(3) When the serum potassium has been estimated frequently throughout attacks, we have often observed that muscular function begins to return while serum potassium values are close to the lowest value observed during the attack

(4) Sporadic cases (Watson 1946, Bull et al 1953) and families (Tyler et al 1951, McArdle 1956) exhibit the typical clinical syndrome without *any* decrease of serum potassium during attacks It seems very significant that in such cases Tyler et al (1951) have found the vacuolar myopathy (a lesion characteristic of familial periodic paralysis [Goldflam 1897, Schmidt 1919, Zabriskie and Franz 1932, Allott and McArdle 1938]) which is demonstrated in fig 6a and shown in fig 6b to have disappeared with reduction of intracellular sodium toward normal

All of these considerations viewed in the light of the experimental data described here, suggest that the common denominator is an excessive quantity of intracellular sodium This by no means excludes hypokalæmia, when it occurs, as a contributory factor, nor does it mean that a sudden increase of intracellular potassium does not influence the onset of a paralytic attack It does indicate, however, that retention of sodium is the primary factor which sets into motion the characteristic chain of events in an episode of periodic paralysis, and it provides a much more direct approach to the prevention of paralytic episodes

Comparison of the sodium and potassium content of muscle in periodic paralysis and in primary aldosteronism (see table) suggests that when intracellular sodium is too high the muscle cell must be able to extrude potassium if paralysis is to be avoided The sum of the *intracellular* cations may be a critical factor in the muscular paralysis The mechanism by which in most of these cases retention of sodium under the influence of aldosterone sets off the potassium-sequestration phenomenon requires *further* study Similarly, the mechanism by which *intermittent* aldosteronism exists in this disease is not yet clear

It seems likely, then, *that an abnormally high* concentration of sodium within the muscle cell is partly responsible for the disturbance of muscle function in periodic paralysis The histological lesion of this disease—i e, hydropic vacuolisation within the muscle fibre—is related *to the* high concentration of intracellular sodium, although total cationic concentration may be important Since the same pathological lesion has been observed in patients who, although suffering from typical periodic paralysis, exhibit no hypokalæmia or hypokaluria during attacks (Tyler et al 1951), it is probable that retention of abnormal amounts of sodium is the common *factor* in the various subgroups of periodic paralysis Balance studies for sodium are needed in such cases

From a practical point of view these studies indicate that a diet low in sodium prevents attacks of periodic paralysis A period of "desalting" with mercurial diuretics and/or carbonic anhydrase inhibitors, associated with a low sodium diet, may be required as an *initial step*

Apparently the stimulus for excessive secretion of aldosterone in periodic paralysis is extra adrenal in origin Although adrenalectomy would remove the source of aldosterone, we believe that this procedure is not indi cated because (1) episodes of paralysis become less frequent and finally disappear as the patient grows older, and (2) replacement therapy, unless grossly suboptimal, would probably be associated with periodic retention of sodium, especially under conditions of stress (Ingle 1952)

We wish to acknowledge the important technical assistance of the following members of our staff Mrs Frances M. Holcombe, research dietitian, and Dr Irving P Ackerman, Dr John A. Moorhouse Dr Abraham Rapoport, Dr Shafik Haddad, Dr Anita Franco, and Dr Lamont W Gaston

THE EFFECT OF TOLAZOLINE HYDROCHLORIDE ON TIC DOULOUREUX

E W Poole
M B N Z, M.R C.P.E
LATE NUFFIELD DOMINIONS TRUST ASSISTANT AND GOODGER SCHOLAR, DEPARTMENT OF NEUROLOGY, UNITED OXFORD HOSPITALS

It has long been recognised that attacks of tic douloureux may be suppressed by vasomotor agents such as choline derivatives, nicotinic acid, histamine, and amyl nitrite (Cooper 1938, Adams and Robinson 1941, Karl et al 1945, Wolff 1948) Such effects, even if temporary, provide a line of therapeutic investigation and are of interest in the study both of the disease and of the pharmacology of the agent used In this field the action of more recent and possibly more effective vasodilator agents appears little explored, and this report presents some experiences with tolazoline hydrochloride The aim has been to determine the existence and characteristics of any effects rather than to establish an optimal therapeutic régime

Material and Methods

Observations were made in 9 patients with tic 2 of whom had disseminated sclerosis and 1 an acoustic neuroma 3 had had alcohol injection years previously Only unequivocal cases of tic were accepted Patients with frequent daily pains and active trigger areas but without severe cardiovascular disease were selected Most of them were awaiting surgical treatment which was delayed only in some instances where the response seemed especially promising Tolazoline hydrochloride (Priscol Ciba) was usually given first orally (12 5 mg) as a test for idiosyncrasy and in 1 case this route alone was used However graduated intravenous administration (up to 50 mg in 10–15 minutes) was preferred so that observations could be made over a short period thereby minimising errors from fluctuations in clinical state Peripheral vascular responses were assessed by subjective flushing and by objective changes—e g, conjunctival suffusion and changes in skin colour and temperature (measured with Marks skin thermometers on the extremities) The patient was kept resting flat during intravenous tests, and the blood-pressure and pulse rate were noted at intervals

The effects on the tic were judged by the number of attacks and their ease of provocation, both with ordinary activity (talking, eating, &c) and with deliberate stimulation of the trigger area (touching, rubbing) before, during, and after administration of the drug It was, however, considered unjustifiable to activate deliberately trigger areas repeatedly during the course of an injection to determine the precise temporal relationship between the peripheral vascular effects and relief of pain, so this was not closely defined

Results

8 patients were given tolazoline intravenously, and in 6 there was a dramatic cessation of attacks and inactivation of trigger areas, persisting for some hours, but in 2 there was little definite change In 5 of these patients (3 responding and 2 resistant) further intravenous tests were possible (after at least 48 hours' interval) and gave similar results Of the 2 showing no remission with intravenous therapy one was subsequently found to have an acoustic neuroma and the other showed smaller peripheral vascular responses than usual The final case in the series was treated only orally and went into a remission for 4 months

Illustrative Case-reports

Case 1 —A woman aged 66, with tic affecting the second and third divisions of the right trigeminal nerve for 18 months She had had numerous increasingly severe attacks daily for many weeks when first seen, most of them coming on spontaneously, trigger areas being inconstantly active Her blood-pressure was 190/90 mm Hg Oral tolazoline 25 mg t d s produced subjective flushing and immediate reduction in the number and severity of her attacks, and at higher dosage (50 mg t d s) the attacks ceased entirely in 2 days, the patient remaining pain free under this régime for nearly a week At this point inert tablets were substituted and the pains promptly recurred though not to their usual extent before therapy Restoration of oral tolazoline did not control these pains as completely as before (nor was the flushing response so definite), but a single 50 mg intravenous dose produced marked vascular responses and immediate complete freedom lasting 3 days Over the next 2 weeks limited pains reappeared on three occasions, and on each 50 mg intravenously produced immediate relief lasting some days without further therapy The pains did not return after the final injection, and the patient has remained pain free for more than 2 years without further treatment

Case 2 —A woman, aged 52, with tic affecting the second and third divisions of her right trigeminal nerve for 16 years, treated 14 years previously by alcohol injection. She had had, for 3 weeks, numerous severe attacks daily, triggered consistently from gum and lip Blood-pressure 140/80 mm Hg Intravenous tolazoline 25 mg produced flushing and dramatic relief of both spontaneous and provoked pains Within 10 minutes food could be chewed on that side and dentures inserted for the first time in 3 weeks, the trigger areas being entirely inactive However, 3 hours later slight tingling and soreness could be provoked from the trigger areas and within 12 hours the pains had returned to some extent Surgical intervention prevented further observations

Case 3 —A woman aged 51, with tic affecting the third division of her right trigeminal nerve for 8 years, treated on three occasions by alcohol injection Numerous severe attacks had been occurring daily for 3 weeks and oral trigger areas were acutely active Blood pressure 105/85 mm Hg An oral test dose of tolazoline 12 5 mg was given but the pains were so distressing that an intravenous injection was started without awaiting the oral response 10 mg intravenously unfortunately produced "bumping" in the chest shivering and numerous extra systoles along with warming of the extremities However, the attacks ceased and within 25 minutes of the injection the trigger areas became inactive, and the face could be rubbed and food taken without incident for the first time in 2 weeks The cardiac abnormalities subsided within 2 hours of the injection Apart from one spontaneous attack several hours later, the patient remained pain free for 2 more days without further medication She had some tingling feelings of the type often heralding an attack, but they came to naught On the 4th day she had a moderate spontaneous attack, and oral therapy was cautiously instituted (12 5–25 0 mg t d s) Over the next 3 weeks the trigger areas remained inactive, but she had moderate spontaneous pains every few days These then increased, and occasional triggered pains reappeared Higher oral dosage was not tolerated A further intravenous injection again gave her 2 days of complete freedom with gradual return of first spontaneous and then triggered pains over the next week, whereupon root section was done

Case 4 —A man aged 47, with disseminated sclerosis for 11 years and mild left sided tic for 3 years When first seen he had been having pains daily for some weeks with numerous severe paroxysms for the past 3 days, trigger areas were well defined Blood pressure 155/100 mm Hg Intravenous tolazoline 50 mg inactivated the trigger areas, but limited spontaneous attacks recurred 1½ hours later, and therapy was continued orally (50 mg t d s) Under this régime the next 2 days were pain-free, but mild spontaneous pains returned again, and the trigger areas could not always be treated with complete indifference However, under continued oral therapy this again subsided, and the patient had weeks of freedom with only an occasional minor attack Therapy was stopped after 3 months, and inquiry 1 year later revealed no evidence of relapse

Discussion

These results indicate that tolazoline may, like nicotinic acid, histamine, &c , suppress the paroxysms of tic Such effects may be due to relief of nerve ischæmia and thus support the view that there is an ischæmic factor at some stage in the mechanism of some types of tic Triggered attacks seem more readily suppressed than spontaneous, and, even when the pain is abolished, the involuntary twitch of the facial muscles which often accompanies it may persist, as has been observed with other vasomotor drugs (Adams and Robinson 1941, Wolff 1948)

It is of interest that cases with disseminated sclerosis also respond, in view of possible vascular factors in its pathogenesis The variation in therapeutic response may derive from individual differences in drug susceptibility or capacity for local vascular reaction

The present series is too limited to show whether there is any significant difference between those cases responding and those that do not, but analysis of a larger series might prove of interest The fact that relief may long outlast the expected time course of the drug does not necessarily invalidate an anti-ischæmic explanation Factors determining the fluctuating course and long remissions so characteristic of tic are ill understood, and it might be that a vasodilator response over a short or long period favours those biochemical states existing in a remission Indeed the remissions following procaine nerve-block, incomplete alcohol injection, and surgical operation leaving nerve pathways intact might also derive from the beneficial effects of the period of vasodilation they provoke

Therapeutically the results in such a small series must be interpreted with great caution, as the history of tic shows, but it is evident that good temporary relief may be afforded Moreover a period of normal function with vigorous stimulation of the trigger areas may favour stabilisation in this state It remains to be seen whether prolonged oral or parenteral therapy with this or similar agents can induce more general and lasting results Its simplicity and immediacy commend it as one approach that should not be overlooked

Summary

The effect of tolazoline hydrochloride on tic douloureux was investigated in 9 severe cases, 2 associated with disseminated sclerosis

In most cases both spontaneous and triggered pains were suppressed for varying periods after parenteral administration

I am indebted to Dr W Ritchie Russell, Dr C W M Whitty, Mr J Pennybacker, F R C S , and Prof J E Caughey for permission to study patients under their care, Dr M Fischer Williams for assistance with case 1 , and Dr Whitty for advice and criticism Part of the work was done with financial assistance from the Medical Research Council of New Zealand

BLOOD COAGULATION AFTER THE INGESTION OF SATURATED AND UNSATURATED FATS

C MERSKEY
M D Cape Town, M R C P
PHYSICIAN

H L NOSSEL
M B Cape Town
REGISTRAR

DEPARTMENT OF MEDICINE, UNIVERSITY OF CAPE TOWN AND GROOTE SCHUUR HOSPITAL, SOUTH AFRICA

IT has been claimed that blood coagulation is accelerated by the feeding of fat (Waldron et al 1951, Fullerton et al 1953, O'Brien 1955, 1956) O'Brien (1956) has gone so far as to say "That a fatty meal accelerates blood coagulation is now established" On the other hand, there are contrary opinions (Tulloch et al 1953, Manning and Walford 1954, Hall 1956a)

Dietary fat has been said to be important in the genesis of atheroma (Keys 1952) It is also asserted that feeding of fats containing large amounts of unsaturated fatty acids reduces the serum cholesterol (Kinsell and Michaels 1955, Malmros and Wigand 1955, Bronte-Stewart et al 1956)

For these reasons it appeared to us to be important to re evaluate the effect of feeding different types of fat on blood coagulation

Material

All tests were done on patients in medical wards They were convalescing from a variety of diseases—chiefly peptic ulcer, uncomplicated hypertension, infective disease (e g , pneumonia, pyelitis, meningitis), skin disease, and cardiac and cerebral disease (*including* atheroma) Patients with uræmia, jaundice, or blood or bleeding diseases, and patients having anticoagulant or cortisone therapy or with cardiac failure of more than very mild degree were excluded Patients were asked whether they would be prepared to take either a high fat or a low-fat breakfast , those who consented were allocated to one or other group by random selection

Methods

The meals given were

(1) *Low fat* —This consisted of bread and jam, porridge tea, and fruit Sugar and skimmed milk were allowed The fat content of the meal was less than 5 g

(2) *Oil* —Salad oil was given as a draught together with the low fat breakfast In the experiment where consumption of prothrombin in silicone tubes was measured, 90 ml of a mixture of sunflower seed oil and pilchard oil (iodine number 137) was used In the remaining experiments, 120 ml of sunflower seed oil (iodine number 128) was given These oils were especially selected because of their high content of unsaturated fatty acids

(3) *High fat* —In the prothrombin consumption experiment, 4 patients received 180 ml and 3 received 210 ml of 40% cream, together with a low fat breakfast 7 additional patients received a breakfast containing 80 g of fat (bacon and eggs bread and butter, and cream) In all the remaining experiments the high fat diet contained at least 100 g of fat This consisted of fatty bacon fried with one or two eggs, bread and butter, 60 ml of 40% cream, and 180 ml milk Patients refusing bacon for religious reasons were given additional

butter and eggs Each patient was carefully observed to see that all the diet given was consumed A few baulked at the last pat or two of butter!

As far as possible an equal number of patients in each of the three dietary groups (usually two of each) were tested on the same day

Blood Collection

All patients were fasted from 8 30 P M, and "fasting" specimens of blood were collected between 8 A M and 9 A M the next day Breakfast was then given after which nothing was given by mouth until the final specimen of blood had been taken

In the prothrombin consumption experiment, 20 gauge needles and all glass dry autoclaved syringes were used In the remaining experiments syringes were not used 18 gauge needles were used alone, and the freely flowing or spurting blood was collected directly into the test tube Blood obtained by imperfect venepuncture was not used

Coagulation Tests

Lee and White coagulation time in silicone tubes—1 ml. of blood was placed in each of 6 (in some cases 20) test tubes (3 × $^3/_8$ in) in rapid succession. The tubes were left undisturbed for ten minutes and then each was gently tilted once a minute The end-point adopted was that which permitted complete inversion of the tube The coagulation time recorded for each patient was the mean for all tubes

Coagulation-time of recalcified citrated plasma (calcium time)—Decalcified plasma was obtained by the use of 3 8% sodium citrate (one part in ten of blood) and centrifuging the blood as follows

Slow-spun plasma 1500 revolutions per minute (r p.m.) for ten minutes
Fast spun plasma 3000 r p m. for forty five minutes
Super-spun plasma was obtained from slow spun plasma by centrifugation at 15,000 r p m for fifteen minutes

Plasma was recalcified with an equal volume of M/40 calcium chloride 4 tubes and in some cases 16 tubes were used for each test and the mean recorded

Prothrombin consumption—This was measured on serum from the siliconed Lee and White tubes and on recalcified citrated plasma as previously described (Mershey 1950) The result was expressed as an index as follows

$$\text{Prothrombin consumption index} = \frac{\text{prothrombin time of plasma} \times 100}{\text{prothrombin-time of serum}}$$

Thrombin generation in silicone tubes—This was tested on single specimens of fast spun plasma as described by O'Brien (1955) In this test the fibrinogen time is the shortest clotting time in any of the fibrinogen subsamples The thrombin generation time is the interval which elapses between the recalcification of the plasma and the fibrinogen time subsample tube

Blood thromboplastin generation—This test was performed as described by Biggs and Macfarlane (1953) Three components are required—(1) Platelets (2) Alumina treated plasma, and (3) Serum Samples of two components from fasting patients were tested with fasting and postprandial high fat meal samples of the third (1) 4 batches of platelets from fasting and 4 from postprandial blood were tested (2) A 1 in 5 and a 1 in 25 dilution of alumina-treated plasma derived from three specimens of fasting and postprandial blood, were tested (3) Serum was obtained from 18 fasting patients 9 were taking a low fat and 9 a high fat diet and serum was obtained four hours later This was stored at 37 C for twenty four hours, diluted 1/10 in saline and stored at − 20°C until tested

Factor V—This was measured by the corrective effect on the one-stage prothrombin time of a 1 in 10 and a 1 in 50 dilution of citrated plasma on aged human oxalate plasma Specimens of plasma were tested for factor V from patients fed low fat low fat plus oil and high fat diets

Factor VII—This was measured in plasma and serum by the method of Koller et al (1951) The same serum specimens were tested for factor VII as were tested in the thromboplastin generation test

Accelerated one stage prothrombin times (stypven time)—Russell viper venom ('Stypven') was used diluted 1 in 20,000 Equal volumes of fast spun plasma (or plasma diluted 1 in 4 with 0 85% saline) saline, stypven and M/40 calcium were incubated and the coagulation time recorded The calcium was added a minute after the stypven had been mixed with the plasma A separate bottle of stypven (with the same batch number) was diluted for the fasting and postprandial experiments because the diluted stypven appeared to lose potency even if stored at 4°C All tests were done in duplicate

All coagulation tests were carried out at 37°C Coagulation-times were recorded by technicians who were, as far as possible ignorant of the results which might be expected for any particular test For any test on any one patient, the fasting and later specimens were both tested by the same technician

Statistical Analysis

The significance of change in the coagulability of the blood was estimated with Student's t test and a level of probability assigned to the results for each experiment and each method of estimation of coagulability This significance was measured in two ways

(1) Each series was regarded as a single experiment of paired observations and a single value for each patient obtained for the difference between the fasting and postprandial blood samples t was then calculated from the formula

$$t = \bar{x}\sqrt{\frac{n(n-1)}{\Sigma x^2 - \frac{(\Sigma x)^2}{n}}}$$

where Σx is the sum of the values for the differences between fasting and postprandial blood in each patient, n the number of paired observations, and $\bar{x}$ the mean difference—$\bar{x} = \frac{1}{n}\Sigma x$

From this value for t a significance level was obtained (designated P_1) which indicates the probability that the mean of the differences is not significantly different from zero

(2) The mean differences between the paired observations for patients fed a high fat or oil meal were compared with the mean differences for patients fed a low-fat meal A value for t was calculated using the formula

$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{(S_1)^2}{n} - \frac{(S_2)^2}{n_2}}}$$

where $\bar{x}_1$ is the mean difference in the high-fat or oil series and $\bar{x}_2$ the mean difference in the low fat-series, and S_1 and S_2 the respective variance of the series indicated by the subscript

From this value for t a significance level was obtained (designated P_2) which indicates the probability that the differences in the high-fat or oil series are drawn from the same population of differences encountered in the low-fat series This seemed a valid comparison to draw as there was no obvious sampling bias in allotting the type of meal to each patient

P_2 then takes into account any effects of a control meal and the variance of a controlled series of observations It is a more stringent test of significance and may allow for a large number of otherwise uncontrolled circumstances It may be argued that where the control series of preprandial and postprandial samples have not been shown to differ significantly they should be ignored This is a valid argument and for this reason we have quoted both P_1 and P_2

A value for P of less than 0 05 has been selected as a minimal significance level

TABLE I—LEE AND WHITE COAGULATION TIME OF WHOLE BLOOD IN SILICONE TUBES (MIN) IN 12 TESTS OF THE LOW FAT AND OIL SERIES AND IN 14 OF THE HIGH FAT SERIES THE MEAN OF 20 TUBES WAS TAKEN AS THE COAGULATION TIME IN ALL OTHER TESTS 6 TUBES WERE USED

Diet	Low fat		Oil		High fat	
No of patients	37		38		39	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	34 9	34 0	34 3	30 [illegible]	34 4	3[illegible]
P_1	> 0 4		< 0 01		> 0 4	
P_2			> 0 1		> 0 3	

TABLE II—COAGULATION-TIME OF RECALCIFIED PLASMA SLOW-SPUN IN GLASS TUBES (SEC)

Diet	Low fat		Oil		High fat	
No of patients	25		26		25	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	154 0	142 2	145 8	149 8	150 9	141 8
P_1	> 0 05		0 5		0 2	
P_2			>0 05 (increase)		> 0 7	

Results

Lee and White coagulation-time—The results of this test are shown in table I The changes produced by oil appear to be significant on their own (P_1), but P_2 for oil is not significant

Calcium-time of plasma (tables II–IV)—No significant changes are seen in the low-fat or high-fat series The oil seemed to cause a lengthening of the calcium-time when measured on plasma fast spun in silicone tubes This was in marked contrast to the apparent shortening caused by the oil in the Lee and White test

TABLE III—COAGULATION TIME OF RECALCIFIED PLASMA FAST SPUN IN SILICONE TUBES (SEC)

Diet	Low fat		Oil		High fat	
No of patients	21		20		21	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	302 0	280 1	315 2	363 2	287 3	302 9
P_1	0 3		0 02 (increase)		0 6	
P_2			< 0 02 (increase)		> 0 2	

Prothrombin consumption (tables V and VI)—The amount of residual prothrombin is high in all these tests Lipæmic plasma does not appear to consume more prothrombin during coagulation than the control specimens

Thrombin generation in silicone tubes (table VII)—The means of all tests have been combined in fig 1 No significant differences are to be seen in either of the series tested

TABLE IV—COAGULATION TIME OF RECALCIFIED PLASMA SUPER SPUN IN GLASS TUBES IN 12 TESTS OF THE LOW FAT AND OIL SERIES AND IN 14 OF THE HIGH FAT SERIES, THE MEAN OF 16 TUBES WAS TAKEN AS THE COAGULATION-TIME IN ALL OTHER TESTS 4 TUBES WERE USED

Diet	Low fat		Oil		High fat	
No of patients	37		38		39	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	247 6	257 7	253 2	232 2	259 4	247 9
P_1	0 4		> 0 05		> 0 9	
P			> 0 05		> 0 1	

Blood thromboplastin generation—No difference in activity in this test could be demonstrated between platelets, Al(OH)$_3$-treated plasma, or serum derived from either fasting or lipæmic blood

Factor V—No significant differences were found in factor-V activity in the three groups of patients tested

Factor VII—No significant differences were found in factor VII activity in the two groups of patients tested

Stypven times (table VIII)—P_1 was significant with the high fat diet, using both diluted and undiluted plasma, and with oil when using diluted plasma When P_2 was considered, both high fat and oil were significant in diluted plasma but not in undiluted plasma Not only were the final results significant but there was considerable consistency in the results, the lipæmic (fat or oil) plasma having almost invariably a shorter stypven time than the fasting plasma These consistent results were in marked contrast to the inconsistent and highly variable results obtained in all the other tests used in this series of investigations

Discussion

Our results do not confirm the claims that feeding of mixed animal and vegetable fats accelerates coagulation Inconsistent results were obtained with all the tests used except when the stypven-time was measured

TABLE V—PROTHROMBIN CONSUMPTION INDEX OF WHOLE BLOOD CLOTTED IN SILICONE TUBES

Diet	Low fat		Oil		High fat	
No of patients	7		7		14	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	60 0	75 9	67 6	78 0	50 1	77 3

Some authors assess the results of all these coagulation tests in percentage of normal and speak of "overall coagulability" This would presumably mean adding the effect of fat or oil in the stypven-time test (where the results appear to be significant), to all the others (where the results are generally not significant) This, in our view, would confuse the results and add nothing of value

Our choice of a "lipæmic" specimen four hours after the ingestion of fat may not have measured the greatest degree of the effect of fat and hourly specimens might have revealed a change in coagulation But a large number of four-hour plasma samples were grossly lipæmic, and the coagulation tests in these were little different from those which were not obviously grossly lipæmic (Both Fullerton et al. (1953) and O'Brien (1955) claimed to have shown acceleration of coagulation at this time after food) Choice of a four-hour specimen cannot, we think, account for our failure to demonstrate changes in blood coagulation after fat ingestion

TABLE VI—PROTHROMBIN CONSUMPTION INDEX OF RECALCIFIED PLASMA SUPER SPUN IN GLASS TUBES

Diet	Low fat		High fat	
No of patients	14		15	
	Fasting	4 hours	Fasting	4 hours
Mean	64 5	76 8	66 6	60 7
P_1	> 0 1		> 0·3	
P_2			> 0 05	

All our tests were done on patients in hospital Many other workers have used healthy people We cannot deny the possibility that this is the reason for our failure to demonstrate an effect on coagulation, but we think it very unlikely We took care to concentrate on con

TABLE VII—THROMBIN GENERATION TEST OF RECALCIFIED PLASMA FAST SPUN IN SILICONE TUBES

Diet	Thrombin generation time (min)				Fibrinogen time (sec)			
	Low fat		High fat		Low fat		High fat	
No of patients	11		12		11		12	
	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Mean	12 4	14 1	13 8	13 8	55 0	50 8	51 8	47 4
P_1	0 3		> 0 9		0 4		0 2	
P_2			> 0 3				> 0 9	

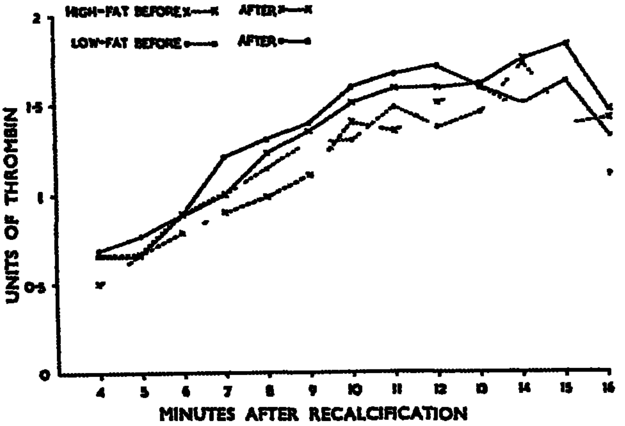

Fig 1—Thrombin generation in silicone tubes. This figure represents the means of all tests in each series The fibrinogen-time is represented by the amount of thrombin generated at the highest point of the curve The thrombin generation time is the time that has elapsed from recalcification to this point of the curve

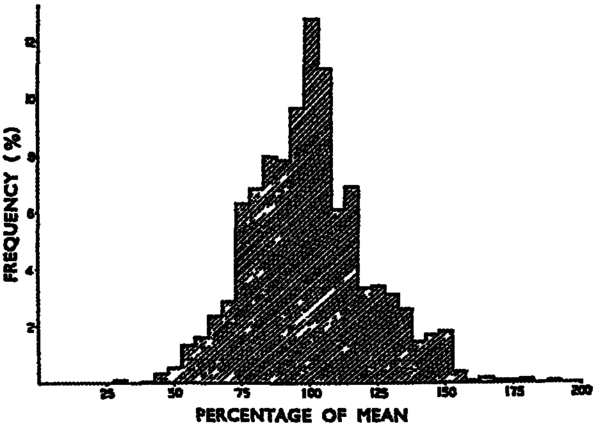

Fig 2—Lee and White coagulation-time in silicone tubes histogram of 1520 individual tube readings The 20 tubes used in each test have each been expressed as a percentage of the mean for that test The scatter is very wide

valescent patients and to avoid patients whose diseases were known to be associated with abnormal coagulation or a bleeding state It could even be argued that it is more important to know whether fat accelerates coagulation in people who are sick than whether it does so in those who are well.

TABLE VIII—ACCELERATED ONE STAGE PROTHROMBIN-TIMES (STYPVEN TIME) OF PLASMA FAST SPUN IN SILICONE TUBES

Plasma	Diet	Low fat		Oil		High fat	
	No of patients	21		22		22	
		Fasting	4 hours	Fasting	4 hours	Fasting	4 hours
Undiluted	Mean	28 5	27 9	29 5	29 6	28 8	25 9
	P₁	> 0 5		> 0 9		0 01	
	P₂			> 0 6		> 0 05	
Diluted	Mean	47 1	46 4	46 7	40 6	44 4	38 3
	P₁	> 0 6		< 0 01		< 0 01	
	P₂			0 02		0 05	

(Excluding table VIII for the moment, it will be seen that there are no significant changes after a low-fat or a high-fat meal) The oil appears to shorten the clotting-time in the Lee and White test (table I) and to lengthen it in a calcium-time test (table III), while another variant of the calcium-time test shows no significant alteration (Both fat and oil shorten the one stage prothrombin time with stypven (table VIII)

Very few authors emphasise the uncontrolled variables in these coagulation tests Even different tubes in the same test can give widely differing results Many authorities advocate the use of 3 or 4 tubes in the test and tilt the 3rd or 4th tube only when the 1st and 2nd tilted tubes have coagulated When this technique is used, blood in an untilted tube is occasionally found to have clotted by the time the tube is first tilted No acceptable end point would then be available The error due to differences in individual tubes can be minimised by the use of 20 tubes in the test The mean of these 20 tubes could then be taken as the best available estimate of the true coagulation-time The degree of scatter is shown in fig 2, where representative examples are shown of three types of result which have been encountered with about equal frequency

Fig 3 was derived from 76 such tests (1520 tubes), each tube reading being expressed as a percentage of the mean Only 26% of these tube readings fell with ± 5% of the apparent true mean Somewhat similar observations can be made for readings of calcium-time Thus it would appear at first glance that the insensitivity of the technique used would be the major obstacle in assessing the effects of food on the coagulation-time Through the kindness of Mr J N Darroch, of the department of mathematics of the University of Cape Town, we have been able to obtain a more detailed statistical analysis of the experiments where 20 tubes were used in the Lee and White test and 16 in the *calcium time test His conclusions can be summarised as follows* *

Analysis of variance shows that the random variation in clotting time between blood samples (by which is meant the residual variation when systematic changes from fasting to postprandial and from patient to patient have both been subtracted) is overwhelmingly larger than it would be if it arose simply from the variation within samples, that is from the insensitivity of the measuring technique For the Lee and White coagulation time it is 12 times larger and for the calcium time 23 times larger This completely contradicts one's first impression that the variation of readings within a sample is so large (coefficient of variation is 22% for the Lee and White coagulation time and 17% for the calcium time) as to destroy any possibility of detecting any systematic

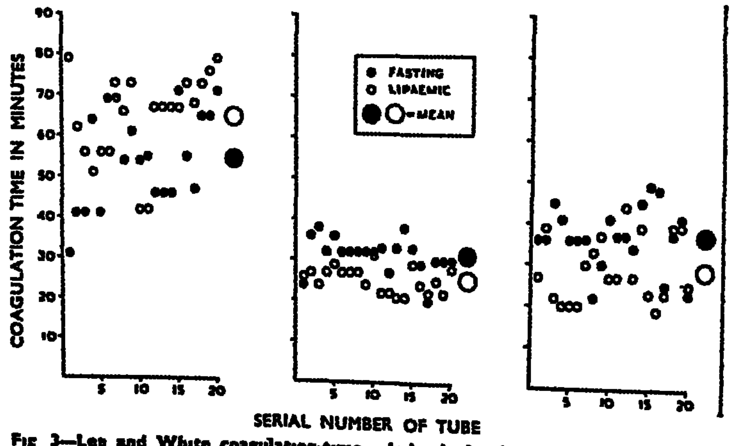

Fig 3—Lee and White coagulation-time Individual tube readings in 3 patients before and after a high-fat meal The three diagrams represent widest scatter, least scatter, and intermediate scatter The means are also shown

changes in clotting time It now appears that the spread of readings within samples is having far less effect on the experiment than the uncontrolled variability between samples

---

* A full copy of the statistical analysis may be had in mimeographed form from the office of THE LANCET, 7, Adam Street, London, W C 2

It is suggested that this latter variability may be accounted for in one (or both) of two ways Firstly, that some artificial shortening of clotting time is introduced when the sample is taken from the patient, and that this randomly affects some samples more than others Secondly, that blood within a person has a clotting time which randomly alters at different times to such an extent as to overshadow any change resulting directly from the content of a meal

To us it seems that the most significant variable is the degree of perfection of the venepuncture Technically imperfect venepunctures were always discarded But there are unavoidable variations in what we regard as being acceptable for the purposes of the test The time of the day, the weather, the taking of a meal as distinct from its fat content, and other variables too numerous to mention might also be implicated Because of what has been said above and because of all these, we feel that we have been unable to show that fat materially alters blood coagulation when this is measured by the Lee and White or calcium time tests

Thrombin Generation Test

To obtain significant results with this test O'Brien (1955) found it essential to use platelet poor plasma collected in silicone tubes In this artificial system the generation of thrombin is slow, so it is not surprising that the plateau of thrombin generation is broad This has been clearly shown by Pitney and Dacie (1953) and is obvious from fig 1 It will be seen that very little thrombin is produced Differences of 5–10 seconds at these levels represent only infinitesimal amounts of thrombin Yet it is these differences that have to be used in this test to assess the effects of fat on coagulation

We have also obtained negative results with tests which measure prothrombin consumption and thromboplastin generation Our negative results with these tests confirm the findings of Manning and Walford (1954) and Hall (1956b) Only the results with stypven were consistent and reproducible

We feel that the results of tests where fat is added in vitro should be distinguished from those where fat is added in vivo

It is not difficult to show that fat added in vitro affects coagulation Poole (1955) showed that fat shortened the coagulation time It has been shown that cream can abolish the prothrombin consumption defect of recalcified platelet poor plasma (Merskey 1956) Macfarlane et al (1941) demonstrated that cream could shorten the stypven time But none of these in vitro tests should be regarded as proving an effect of alimentary lipæmia on coagulation

In our hands the shortening of the stypven time after a fatty meal is the only test which has given positive results We agree with Fullerton et al (1953) when they say that these findings "could not be interpreted as indicating that a real increase in coagulability occurs during lipæmia The inference that naturally occurring thromboplastin is influenced by lipæmia in a manner similar to viper venom is not justified" Hall (1956a) put the matter into a different perspective when he showed that the acceleration of the stypven-time was important only in the absence of platelets, and that fat merely returned the lengthened stypven-time to what it had been before the platelets were removed In other words no real additive effect has been demonstrated It is, of course, conceivable that areas of the circulation exist where platelets are filtered off in some way, and in such areas alimentary lipid might be important But this is pure speculation Our findings with stypven confirm the report of O'Brien (1956) and are opposed to the conclusions of Maclagan and Billimoria (1956) The latter showed, by in-vitro tests, that only a group of phospholipids found almost exclusively in milk products were important Mutton and beef fat, egg yolk, olive oil, and cod liver oil were inactive This once again demonstrates the differing conclusions which can be reached by the use of in-vivo and in-vitro tests and by varying the circumstances under which the tests are done

Recently fats containing large amounts of unsaturated fatty acids have been used to lower the serum cholesterol The stypven-time results mentioned above appear to be almost as applicable to fats containing small or large amounts of unsaturated fatty acids It could thus be claimed that unsaturated fatty acids are as dangerous as regards coagulation as saturated fatty acids In view of our negative results with all the other tests we have used, the evidence at present seems insufficient to indict either variety of fat as a cause of accelerated coagulation

Summary and Conclusions

An attempt was made to confirm the claim that feeding mixed animal fat shortens the coagulation-time of blood, and at the same time to determine the effect of feeding fat rich in unsaturated fatty acids

Patients were fed three types of meal—low fat, low fat plus salad oil, and high-fat Coagulation times were estimated in each series before the meal and four hours after

The tests which were done included coagulation time of whole blood in silicone tubes, calcium time of plasma with varying numbers of platelets, thrombin generation test, blood thromboplastin generation test, prothrombin consumption, and accelerated one stage prothrombin time (stypven time)

With the exception of the stypven-time, neither the high-fat nor the low-fat meal produced any significant change in coagulation The oil meal (when considered without comparison with the low fat meal) produced significant shortening of coagulation in the Lee and White test and inconsistent results with the calcium time test If these changes were considered together with those produced by the low fat meal, almost all these differences fell away

The stypven-time was significantly shorter in both the oil and high-fat series when diluted plasma was used, and in the high fat series when undiluted plasma was used Undiluted plasma was not significantly affected by oil

Variables have to be considered as arising in the patient and unrelated to the fat content of diet, during venepuncture, and during the measurement of coagulation time These are all very large but the first two are far more important than the third

The measurement of the stypven time is affected by the presence of fat in the plasma This is true of both saturated and unsaturated fat The importance of this in clinical medicine remains to be fully evaluated

We have to acknowledge the large amount of assistance we have received in this study To Prof J F Brock and Prof F Forman, in whose department this work was carried out To laboratory technicians Miss J Ethelston, B SC, Miss E Scholtz, B SC, Miss L Kaplan, Miss C Hoberman Miss S Tromp, Miss B Factor, and Mr M Boshof for much patient work To Dr E B Dowdle and Mr J N Darroch for considerable assistance with statistical analysis To Dr D McKenzie for laboratory facilities To the staff research fund of the University of Cape Town and to the South African Council for Scientific and Industrial Research for grants towards expenses To the many patients who volunteered for the feeding experiments To the Superintendent, Groote Schuur Hospital, for facilities

THE activity of glucose-6-phosphatase, which catalyses the conversion of glucose-6-phosphate to free glucose in the liver, is affected by various physiological and pathological conditions

In certain types of glycogen storage disease there is a deficiency of this enzyme (Cori and Cori 1952)

Fasting increases its activity in rats (Weber and Cantero 1954)

Ashmore et al (1956b) have published an extensive account of the changes in its activity as a result of fasting and of treatment with various hormones

Langdon and Weakley (1955) demonstrated an increase in its activity in alloxan diabetic rats

In view of these reports the activity of this enzyme in human diabetes before and after therapy was investigated * Hitherto little work of this type had been done on man, partly because of the necessity of using micro techniques for assaying the enzyme in liver-biopsy material

Clinical Material

13 patients (10 males and 3 females) admitted to the University College Hospital of the West Indies with diabetes were investigated On admission all were placed on a diet, but further treatment was withheld until numerous investigations, including liver biopsy, had been made After stabilisation of the diabetes the investigations were repeated

2 female patients had "J"-type diabetes (Hugh-Jones 1955)—i e, they differed from the usual young acute diabetic mainly in that they were insulin-resistant They were aged 17 and 21 and had been diabetic for four and five years respectively Both were poorly controlled in spite of several hospital admissions and the outpatient administration of up to 160 and 260 units a day of insulin zinc suspension (I Z S) Hospital supervision during the admission under consideration led to the stabilisation of both patients on 120 units of I Z S a day while taking the type of diet that they would receive at home

3 patients (1 female aged 16 and 2 males aged 36 and 70) had diabetes of short duration—3 weeks, 5 months, and 5 days—and were insulin-sensitive 2 were moderately ketotic on admission These 3 patients could be grouped as type-I diabetes according to the classification of Bornstein and Lawrence (1951)

8 males were considered to have type-II diabetes The type-II patient of Bornstein and Lawrence (1951)—middle-aged, obese, insulin-resistant, and not liable to ketosis—is less common in Jamaica than the non-obese middle-aged diabetic Most of the middle-aged insulin-resistant patients admitted to hospital have never been overweight and when first seen are often well below their ideal weight (Tulloch et al 1956) All 8 patients in this series were underweight. only 2 had ever been obese, 2 had once been of average weight, and 4 had always been below their ideal weight Their ages ranged from 48 to 73, and the duration of their diabetic symptoms from 6 weeks to 5 years All were treated with diet 6 received insulin, and the daily dose at the time of their discharge ranged from 0 to 110 units of I Z S 2 patients were given carbutamide by mouth Both required large doses, 8 and 10 g a day respectively, to achieve adequate reduction of their blood-sugar levels and, after the liver biopsy and other investigations had been repeated, both were transferred to treatment with I Z S before their discharge

7 non-diabetic patients submitted to liver biopsy for other reasons were also investigated

Biochemical Methods

The liver biopsies were made in each case at about 9 A M while the patients were still fasting A Vim Silverman needle was used

The excised liver tissue was immediately placed in a small tube and frozen in solid carbon dioxide Experiments with rat liver had shown that this treatment had no significant effect on the enzyme activity (Patrick 1956) The method used for assay of the enzyme was a micro modification of that described by Langdon and Weakley (1955)

TABLE I—GLUCOSE-6 PHOSPHATASE ACTIVITY IN LIVER OF DIABETICS

Case no	Type of diabetes	Therapy	Glucose 6 phosphatase activity (units)*	
			Before therapy	After therapy
1	I	Insulin	0 397	0 141
2	I	Insulin	0 316	0 157
3	I	Insulin	0 286	0 191
4	J	Insulin	0 295	0 200
5	J	Insulin	0 221	0 157
6	II	Insulin	0 355	0 183
7	II	Insulin	0 175	0 146
8	II	Insulin	0 209	0 150
9	II	Insulin	0 354	0 214
10	II	Insulin	0 252	0 208
11	II	Insulin	0 201	0 172
12	II	Carbutamide	0 235	0 175
13	II	Carbutamide	0 233	0 178

* 1 unit of glucose 6 phosphatase is equivalent to 1 micromole of inorganic phosphate liberated per mg of liver nitrogen a minute

3–5 mg of the biopsy material was quickly weighed on a micro balance with a sensitivity of ±0 02 mg The liver was then homogenised in 120 µl of citrate buffer solution at pH 6 5 Several experiments had indicated that pH 6 5 is at or near the optimal pH for glucose 6 phosphatase activity as it occurs in the human liver Duplicate 20 µl amounts of the homogenate were removed for determination of nitrogen content, and duplicate 10 µl amounts of the homogenate were used for the enzyme assay The reagents were measured with micropipettes of the types described by Bessey et al. (1946)

---

* Since the investigation was begun reduction of glucose 6 phosphatase activity by carbutamide has been demonstrated in liver homogenates in vitro and in laboratory animals (Ashmore et al 1956a Hawkins et al 1956) The dosage used however, far exceeded the therapeutic dosage in man

The final concentrations of the reagents in the enzyme assay were

Liver	1–2%
Glucose 6 phosphate	0 02M
Citrate buffer pH 6 5	0 09M

The enzyme tubes were incubated for 30 minutes at 37°C, and the reaction was terminated by the addition of an equal volume of 10% trichloracetic acid

Inorganic phosphate was determined by a micro modification of the method of Taussky and Shorr (1953) which uses ammonium molybdate, ferrous ammonium sulphate as reducing agent, and a Beckman spectrophotometer fitted with the micro attachment described by Lowry et al (1945)

The amount of nitrogen in the homogenate was determined by Kjeldahl digestion followed by ammonia determination using micro Conway units as described by Kirk (1950)

Results

The results are expressed as micromoles of inorganic phosphate liberated each minute per mg of liver nitrogen Experiments with rat and human liver tissue had shown that the liberation of inorganic phosphate was proportional (within the limits of experimental error) to the concentration of enzyme and to time

Table I summarises the results obtained in the 13 diabetics The average enzyme activity in the whole group was 0 271 units before therapy and 0 175 units after therapy, whereas in 7 non-diabetic patients it was 0 155 units Results obtained for enzymic activity of duplicate amounts of the same homogenate showed consistent agreement to within ±1% It was impossible to compare enzyme activities in duplicate biopsy specimens obtained from different sites in the same human liver, but this was done in rat's liver, and it was found that the results were in agreement to within ±5% (table II)

TABLE II—GLUCOSE 6 PHOSPHATASE ACTIVITY IN BIOPSY SPECIMENS FROM DIFFERENT LOBES OF LIVER OF RATS ON NORMAL DIET

Rat no	Glucose 6 phosphatase activity (units)*	
	Left lateral lobe	Median lobe
1	0 200	0 202
2	0 215	0 228
3	0 190	0 214
4	0 216	0 228
5	0 224	0 227
6	0 292	0 307
7	0 341	0 323
8	0 370	0 370
Mean	0 256	0 262

* Units as in table I

Summary

There is increased activity of glucose 6 phosphatase in the liver of diabetics compared with non diabetics

Stabilisation of the diabetes was followed by decreased activity of the enzyme in 13 patients, whether the diabetes was type I, II, or J, and whether insulin or carbutamide had been administered

We are indebted to Dr R A Irvine for the liver biopsies

CONSULTANT PATHOLOGIST, CHILDREN'S HOSPITAL , HONORARY LECTURER IN PATHOLOGY IN THE UNIVERSITY OF BIRMINGHAM

O H WOLFF
M D Camb , M R C P , D C H
LECTURER IN PÆDIATRICS IN THE UNIVERSITY OF BIRMINGHAM

NECROSIS of the pancreas and of peripancreatic fat tissue occurs only very rarely in childhood In the present two cases it was probably the result of cortisone therapy

Case-reports

Case 1 —A girl, aged 11 years, was admitted to the Children's Hospital, Birmingham, on May 24, 1955, under the care of Dr J W Gerrard From the age of 1 year she had had frequent severe attacks of asthma, which a course of cortisone, started in January, 1955, much improved Early in May, 1955, she came from Eire to Birmingham, and within a few days her supply of cortisone ran out During the next fortnight the attacks of asthma recurred, and on admission she was in a severe attack, cyanosed, wheezing, and dyspnœic

Treatment and Progress

This attack responded to aminophylline and ephedrine, but she had further attacks during the next few days Despite repeated injections of adrenaline and aminophylline and a course of aureomycin (chlortetracycline) the attacks became more severe On June 1 it was decided to start cortisone again, and at 3 P M she was given the first dose (25 mg by mouth) For the next five hours she appeared well, but at 8 30 P M she suddenly became deeply cyanosed and dyspnœic and died within five minutes This final episode differed from her attacks of asthma in that there was only very slight wheezing

Necropsy

A normally developed, well nourished girl with slight clubbing of fingers and toes, a pigeon chest deformity, and slight pitting œdema of feet and legs

The *lungs* were extremely emphysematous, particularly the upper lobes, and thick yellowish exudate was present in the small bronchi The tracheobronchial lymph nodes were swollen, dark red, and soft The *heart* (187 g) showed eccentric hypertrophy of the right ventricle The *liver* (990 g) was congested The *pancreas* was dark red, with darker blackish red spots, and extremely soft On the cut surfaces no lobular structure was discernible The spleen (95 g) was soft, with diffluent pulp The *suprarenal glands* were thin, the right depleted of lipids One *parathyroid gland* was enlarged (8 mm in longest diameter)

Histology

The *lungs* showed congestion and œdema , there was a very occasional small monocytic peribronchial infiltrate, but eosinophils were absent Some alveoli were lined by a pale eosinophil hyaline membrane The *liver* showed mild acute congestion The *kidneys* were congested, showing occasional cortical cysts (150 μ in diameter) and cloudy swelling of the proximal convoluted tubules

One *suprarenal* was 3 mm thick The zona glomerulosa showed œdema of interstitium , the zona fasciculata and zona reticularis were almost completely replaced by irregularly arranged spherical and polyhedric cells with a vesicular nucleus and an abundant cytoplasm filled partly with pale eosinophil granules, partly with vacuoles This zone resembled more the transient cortex or the hyperplastic cortex of adrenogenital syndrome than a normal permanent cortex The medulla was well developed and appeared normal The other suprarenal was 1 25 mm thick, with similar structure

Pancreas —Extensive areas of pancreatic tissue showed necrosis and necrobiosis In the most severely affected areas the secretory cells were anuclear, shrunk, pale, basophilic, and recognisable only by their outlines against distended capillaries, which were filled with clumped masses of red blood cells (fig 1) In other areas the cells were dissociated, without acinar arrangement, and they were shrunk, their cytoplasm

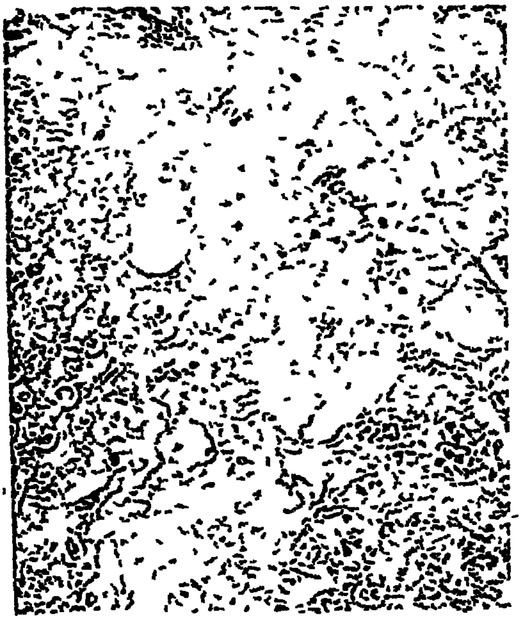

Fig 1—Case 1 pancreas (Hæmatoxylin and eosin ×150.)

homogenised and eosinophilic, and their nuclei pyknotic. The necrotic and necrobiotic process affected equally the secretory tissue, the islets of Langerhans, and the vascular system. The walls of arteries and arterioles were hyalinised or necrotic, and hæmorrhages were seen around necrotic arteries. Where the necrosis affected the periphery of a lobule, the whole interlobular tissue appeared as an anuclear mass of eosinophilic fibres and altered red blood cells, with many clefts and pseudocystic spaces; only the nerve bundles appeared resistant to the necrotising process. Hæmosiderotic pigment was absent. All intrapancreatic and immediate peri-pancreatic fat tissue was necrotic (fig. 2).

One *parathyroid* measured 4·00 × 1·75 mm.; another had a diameter of 1·2 mm.; their structure was normal. There were a few follicular cysts in the *ovaries*, and occasional cytomegalic inclusions in the *parotid gland*. The *pituitary* was unfortunately lost.

Case 2.—A boy was first seen by one of us (O. H. W.) in October, 1955, when he was aged 2 years and 10 months. He had developed normally until a month previously, when his parents noticed that his legs were becoming weak; he also had severe constipation. No definitely abnormal signs were discovered, but during the next three weeks the weakness increased so rapidly that he could not sit or stand without support; his voice became nasal, and food regurgitated down his nose. On Nov. 3, 1955, he was admitted to the Children's Hospital, Birmingham.

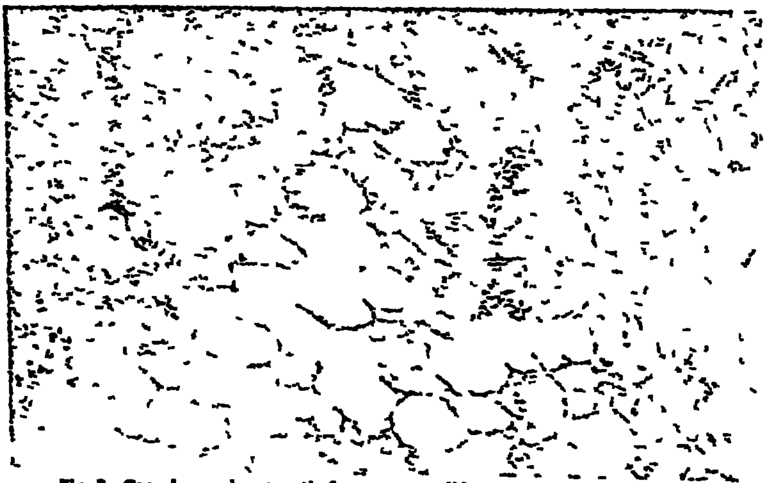

Fig 2—Case 1 peripancreatic fat-necrosis (Hæmatoxylin and eosin ×80.)

Examination

There was now definite weakness of all muscles of his limbs, trunk, face, and palate. The tendon reflexes were present but diminished, the plantar reflexes being flexor. Sensation was unimpaired. The skin was normal. The cerebrospinal fluid was normal. White cells in the blood numbered 14,500 per c.mm. (polymorphs 62%). Urinary excretion of creatine was high, with a creatine coefficient of 12·6 (normal for age 7·9). Radiographs of skull, abdomen, and chest, examination of urine for porphyrins, and electro-encephalography gave normal results.

Treatment and Progress

During the next fortnight the weakness progressed rapidly: the limb muscles became abnormally firm and passive movements of knees and hips became restricted. He developed great difficulty in swallowing and had to be tube fed; simultaneously his respiratory muscles became weaker, and he showed cyanosis. At this stage a diagnosis of polymyositis was made and on Nov. 17 treatment with cortisone 25 mg.

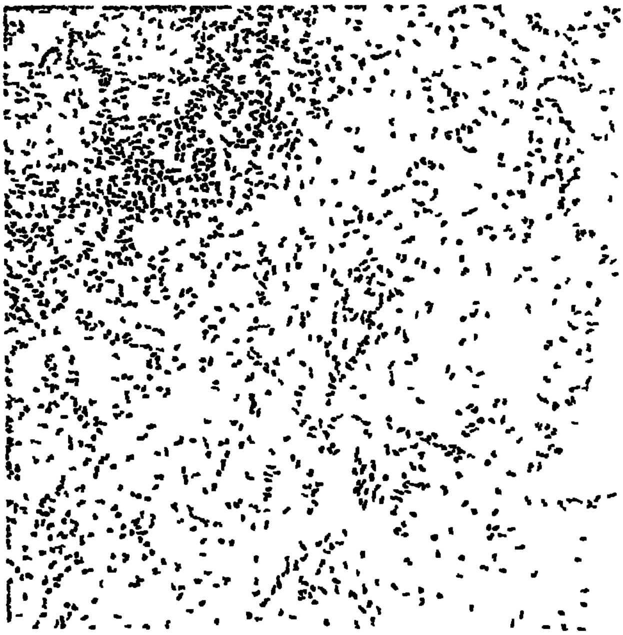

Fig 3—Case 2 pancreatic necrosis with cellular infiltration and deposits of calcium (Van Gieson and elastic-tissue stains ×80.)

thrice daily was started. During the next few days the improvement in respiration and swallowing was dramatic, but on Nov. 28 signs of congestive heart failure appeared. The electrocardiogram was normal. Treatment with digoxin, mersalyl, salt-free diet, and penicillin relieved the heart failure. From Dec. 12 prednisolone (5 mg. four times daily) was given instead of cortisone.

The initial spectacular improvement with corticoids was not maintained, despite physiotherapy; fibrous contractures of hips and knees and an equinus deformity of the ankles developed. Repeated severe infections of the respiratory tract necessitated several courses of antibiotics, and in March, 1956, he developed thrush stomatitis. At this stage skin changes were first noted: areas of brown pigmentation on the extensor aspects of the forearms; reddening of the skin on the cheeks; over the back and the dorsum of the feet the skin was shiny and tightly stretched; and several areas of alopecia developed. There was much skin irritation. A firm diagnosis of dermatomyositis was now made and on March 19 he was discharged home, where he continued to receive prednisolone (5 mg. thrice daily). During the next five months his condition remained almost stationary.

Readmission

On Aug 13 he was readmitted For twenty four hours he had had abdominal pain and vomiting His condition was very poor, temperature 102°F His abdomen was distended, and a round mass was palpable in the midline below the costal margin, it extended about four finger breadths below the xiphoid process The white cell count was 20,000 per c mm (polymorphs 74%) Radiography of the chest showed a small area of consolidation in the posterior basal segment of the left lower lobe After screening, Dr R Astley reported "Normal movements of the diaphragm The upper abdominal mass shows a rounded lower border on the right Its margin appears to run into that of the liver There is no indication of its nature" A blood culture was sterile The vomitus contained altered blood The urine contained sugar during the first twenty-four hours after admission His bad condition contra indicated laparotomy The pneumonia was treated with tetracycline, but the pyrexia continued Ten days later the dose of prednisolone was increased to 5 mg four times daily Within forty eight hours the pyrexia abated, the abdomen became less distended, and the mass decreased and became impalpable Radiography of the chest on Aug 28 showed resolution of the consolidation. The boy was discharged home on Aug 30

Further Readmission

On Sept 15, 1956, he was again admitted, having had abdominal pain and distension and vomiting for twenty four hours The physical findings were essentially the same as at the time of the previous admission Within a few hours he had another vomit, became deeply cyanosed, and died six hours after the last dose of prednisolone

Necropsy

An extremely wasted boy, normal in height for his age, with hips and knees fixed in half flexed position The *skin* was thin with pale brownish macules on the extensor surface of both arms The *lungs* were congested, the *heart* weighed 83 g and appeared normal The *abdominal cavity* contained about 20 ml of clear pale brown fluid The whole epigastrium was filled by a firm mass partly yellowish white and partly white, surrounding the pancreas and the spleen After separation from the liver a plum sized cavity was exposed within the mass which was filled with diffluent material The mass was attached to the stomach, but nowhere was there a communication with the lumen of the stomach, and the gastric mucosa was normal The *pancreas* was embedded in the main mass, it was in some parts hard, in others very soft, the cut surfaces, in which no lobular structure was discernible, had a variegated appearance, with pink, red, yellowish, and white areas The *liver* weighed 870 g and showed severe fatty changes The *spleen* was enlarged (70 g) The left *adrenal gland* was extremely atrophic, discernible as a thin leaf within pale yellow hard fat tissue On the right side a firm pale yellowish-white pad was seen which had the shape of the adrenal but within which only fat tissue was discernible There was œdema of the *brain*

Histology

The *liver* showed severe fatty changes and abundant glycogen granules in the liver cells, round-cell infiltration, and some fibroblastic proliferation in the periportal spaces In the *spleen* the red pulp was studded with numerous nests which consisted of 6–20 spherical or ovoid cells 14–26 µ in diameter The morphology of these cells, their staining properties, and histochemical reactions corresponded to Gaucher's disease, but in no other organ apart from the spleen were such cells seen (Their chemical analysis and histochemical study will be reported later)

Kidneys—Most of the parenchyma showed no significant changes but there were a few small foci consisting of hyaline casts in grossly distended tubules, calcium deposits, occasional hyalinisation of a glomerulus, with very occasional calcification, thickening of capillary basement membrane, and interstitial fibrosis

The left *suprarenal gland* was 1 0–1 5 mm thick its structure was normal There was extensive necrosis of the peri adrenal fat tissue The *right suprarenal* showed nothing abnormal apart from atrophy No necrosis of surrounding fat

Pancreas—The pancreatic tissue was reduced to a few small irregular lobules in which secretory cells were intact and contained zymogen granules Most of it was replaced by necrotic, fibrillary, or granular faintly eosinophilic masses, patches of polymorphs, nuclear debris, and granular calcium deposits (fig 3) Here the islets of Langerhans were affected by the necrotising process to the same extent as the secretory tissue Capillaries were not seen in the necrotic areas, and arterioles were often recognisable only by wavy rings of elastic tissue Intact red blood cells were not seen Hæmosiderin was scanty in the form of widely scattered extracellular granules Often the necrosis involved the whole arterial wall, including the elastic membrane In none of the recognisable arteries was fibrinoid demonstrable Occasionally a thrombus in organisation was seen in a not completely necrotic artery Sudanophil material was scanty, it was seen in patchy distribution in the form of extracellular drops In such areas a few anisotropic crystals with "Maltese crosses" were also seen

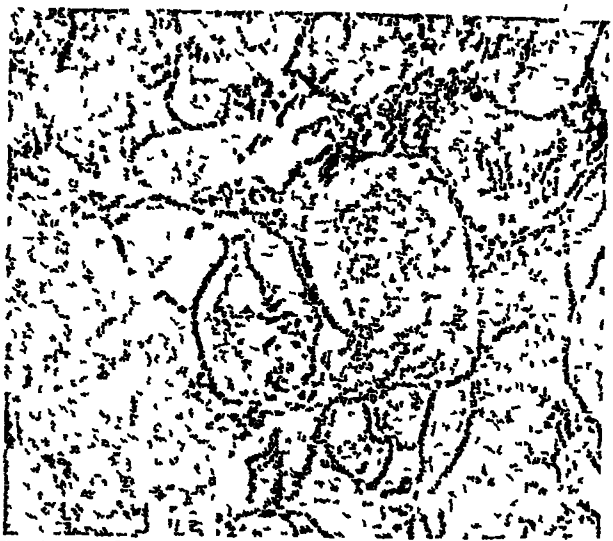

Fig 4—Case 2 necrosis of peripancreatic fat tissue (Hæmatoxylin and eosin ×80)

Peripancreatic fat tissue—All the fat cells were necrotic and replaced by irregularly outlined masses of pale eosinophilic anuclear material (fig 4) The fatty lump adherent to the left abdominal wall consisted of lobules of necrotic fat tissue with calcification, surrounded by a fibrous capsule and granulation tissue which was poor in capillaries An occasional patch of a mucoid (periodic acid Schiff positive) substance was seen within the necrotic fat tissue Cell membranes separating two or more cells were often ruptured or had disappeared, forming micro fat cysts

Pituitary—The number of basophil cells appeared to be increased, but sections from only one level were examined Those cells stained blue with azan and appeared to correspond to delta cells (Purves 1956) Some of these cells were hypertrophic and/or showed hyalinisation of the cytoplasm Such changes were best seen with the stain of Róna and Morvay (1956), and degranulation was evident in the performic acid aldehyde fuchsin stain of Russell (1956) when compared with normal controls

Muscles and skin—Further histological findings, illustrative of the effect of cortisone in dermatomyositis, will be published separately

Discussion

Pancreatic necrosis—often called acute hæmorrhagic pancreatitis—is extremely rare in childhood Gibson and Gibson (1956) collected 27 published cases of severe "hæmorrhagic pancreatitis" in childhood and added 1 of their own Most of these cases were secondary to mumps, scarlet fever, diphtheria, typhoid fever, influenza, otitis media, or trauma (Shallow and Wagner 1947, Végelhyi 1947, Shanks et al 1954), and the so called primary form, which is the common form in the adult and is often associated with gall stones, was seen only exceptionally in a child (Dobbs 1935)

The association of such an exceptional disease with corticoid therapy on two occasions already suggested a causal connection This belief was strengthened almost to certainty when, shortly after the necropsy of case 1, the reports of Stumpf and Wilens (1955) and of Stumpf et al (1956) were published

These workers found pancreatic lesions in 44 of 53 rabbits given intramuscular cortisone 3–8 mg daily for periods of twenty one to eighty one days They emphasised the similarity to early autolysis The earliest observed changes consisted of reduced basophilia of the basal portion of acinar cells This was followed by vacuolisation, shrinkage, disarrangement of acinar cells, and necrosis, with accumulation of polymorphs Peripancreatic fat necrosis was present in 13 of 44 cortisone treated rabbits with pancreatic lesions Pancreatic changes in cortisone treated rabbits have been described by Lazarus and Bencosme (1955, 1956), who consider them to be proliferating intercalated ducts, but Stumpf et al interpret them as proliferation of duct like cells within remnants of destroyed acini

If we compare the descriptions of experimental pancreatic necrosis produced by administration of cortisone with the findings in our two cases, it becomes clear that they differ only in severity, our cases being instances of acute and subacute diffuse hæmorrhagic necrosis of the pancreas associated with peripancreatic fat necrosis

In view of the wide use of cortisone therapy in a variety of diseases, and particularly the reports on beneficial effects of cortisone in "acute hæmorrhagic pancreatitis" (Brockis and Jones 1956), one is forced to assume the existence of a peculiar constitutional disposition, but its nature is obscure Although a link between our two cases is suggested by the reported association of asthma with diffuse collagen-disease (Gillespie and Potellakhoff 1951), hypersensitivity per se cannot be responsible, because allergic patients represent a considerable proportion of those treated with cortisone and no instance of association with pancreatic necrosis in man has yet been reported (One of us [H S B] tried to produce cortisone hyper sensitivity in guineapigs but with no success) In addition, only in case 1 had there been a break in cortisone treatment, with a fulminating illness when the therapy was started again, in case 2 the therapy was continuous No indication of the nature of the disposition can be found in case 1, but in case 2 the association with an isolated lipidosis of the spleen may possibly indicate the presence of an inborn metabolic error

Similarly the mechanism of cortisone-induced pancreatic necrosis can only be a matter of speculation The "reflux" mechanism described by Opie (1901) is usually considered to be the main factor in the development of pancreatic necrosis Closely related is the mechanism of stagnating secretion resulting from squamous metaplasia of duct epithelium, which Rich and Duff (1936) believe to be the principal cause Block et al (1954) produced necrosis of pancreatic tissue and peripancreatic fat-necrosis when obstruction of pancreatic ducts was combined with experimental ischæmia of the organ Thal and Brackney (1954) produced fulminating pancreatic necrosis in rabbits and goats as a local Shwartzman phenomenon when they injected endotoxins of meningococci or *Escherichia coli* into the pancreatic duct and subsequently the same endotoxin by the intravenous route Rapid diffusion of the toxin from the duct after preparatory injection led apparently to sensitisation of vascular endothelium It is not likely, however, that this mechanism operated in our two cases There was no evidence of recent infection in case 1, and, although in case 2 an abdominal mass and pneumonia were diagnosed simultaneously, the size of the mass suggested that the pancreatic disease was present already before the development of the febrile illness Equally, mechanical obstruction and epithelial metaplasia can be excluded on the basis of the necropsy findings Dietary imbalance, which is known to produce "pancreatitis," was not present

A direct toxic action exerted on the secretory tissue of the pancreas is possibly responsible for "pancreatitis" due to ethionine, carbon tetrachloride, and other compounds, but is not probable with corticoids We believe that cortisone has an effect on pancreatic secretion and that, in the presence of an unknown constitutional disposition, this causes stagnation of the secretion and pancreatic necrosis by a "reflux" mechanism

The renal changes observed in case 2 were probably related to the pancreatic necrosis They were almost identical with those described by Lynch (1954) in 4 cases of "acute hæmorrhagic pancreatitis" Unfortunately only paraffin embedded kidney tissue was examined and therefore nothing can be said about the presence or absence of fat-emboli

Both cases showed atrophy of the adrenal glands, particularly case 2, in which atrophy was associated with replacement lipomatosis The structure of the adrenal cortex was in this case normal, but the milder atrophy in case 1 was associated with gross alteration of the architecture and cellular morphology This atrophy can be attributed to the corticoid therapy From our rather limited experience with leukæmic children it appears that severe atrophy may be commoner with prednisolone The pituitary in case 2 showed changes similar to those described by Thornton (1956) in cortisone treated patients

Summary

In 2 children pancreatic necrosis followed corticoid therapy for asthma and dermatomyositis respectively

The pancreatic necrosis was apparently caused by the corticoid therapy

We wish to thank Prof J W Gerrard for the clinical notes of case 1, Mr A R Detheridge for technical assistance, and Mr J G Williamson for the photographs

PANCREATIC NECROSIS

IN A CASE OF STILL'S DISEASE

MARIA MARCZYNSKA-ROBOWSKA
M D Warsaw
LECTURER, CLINIC FOR INFECTIOUS DISEASES OF CHILDHOOD, WARSAW, POLAND

EXCEPT in mumps, acute disease of the pancreas is rare during childhood Dobbs (1935) collected 14 cases and added 1 of his own Jaeger (1943) summarised 10 more, including 1 that he had seen 4 further cases have since been reported (Shallow and Wagner 1947, Shanks et al 1954, Gibson and Gibson 1956 Pender 1957)

Case-record

A boy aged 5 years was admitted to our clinic in August 1955 with pain in his joints He had been well until the previous June, when he had fever with enlargement of lymph glands A month later there was pain and swelling of ankle, knee, elbow, and wrist joints

Examination

On admission, his temperature was 37 8°C, and he had pain in the legs, hands wrists, and elbows The skin and mucous membranes were pale yellow and many lymph glands were enlarged The spleen was felt at the costal margin, and the liver three finger-breadths below the ribs The knees were swollen, spindle shaped, and slightly contracted, and the ankles also spindle shaped and swollen

The erythrocyte sedimentation rate (Westergren) was 120 mm in one hour and 150 mm in two The red cell count was 2,990,000 per c mm The albumin/globulin ratio was reversed Radiography of the affected joints showed only slight decalcification The diagnosis of Still's disease was established

Treatment

Treatment started with corticotrophin (A C T H) in large doses (10 mg six hourly) because the disease was acute, and a low salt diet After two weeks, the child was much better, but lowering the dosage of corticotrophin led to deterioration

Two months after admission, the dose of corticotrophin was increased again to 40 mg daily, but the joint pains in the lower limbs increased Improvement followed intravenous infusion of corticotrophin in a 5% solution of glucose, beginning with 40 mg daily and diminishing gradually to 25 mg Later, intramuscular injections were resumed the dosage was 40 mg daily at first but was then adjusted to the boy's state

Final Illness

At the end of the fourth month he had a left sided pneumonia The temperature rose to 40°C, and the joint symptoms increased This was followed by an attack of smallpox, during which the corticotrophin was stopped for four days On the day before his death (six days after developing smallpox), his general condition was rather good and his temperature normal, but in the evening he began to complain of acute abdominal pain, and his abdomen became swollen, with rebound tenderness but no muscle resistance Next day the temperature rose to 39 8°C, he became very restless, and generalised convulsions preceded death

Post mortem Findings

Necropsy showed fat necrosis of the pancreas and greater omentum, and a subcapsular hæmorrhage in the tail of the pancreas Histologically, the pancreatic lobules were well conserved, the interlobular connective tissue contained mostly lymphocytes, but in some parts leucocytes and hæmorrhage, and necrosis of fat tissue was widespread

Comment

Pancreatic necrosis has been reported in association with lesions of the neighbouring organs (Connell 1941, Herfort 1951), acute infections (Dozzi 1946), and intoxications In childhood mumps and otitis are the commonest causes (Adams 1939) In our case the pancreatic necrosis may have been caused by Still's disease (which could produce obliterative changes in the pancreatic vessels leading to necrotic changes), by the pneumonia or smallpox, or possibly by the corticotrophin the child had been receiving

"One of the reasons why popular discussions on psychological matters are so uninformed is perhaps the fact that psychology, being a science, uses methods and discussions of a highly technical nature In particular, it uses statistical methods, and most people have developed a strong avoidance reaction to statistics This reaction is both interesting and odd because it seems to be rather one sided A discussion of odds in horse racing, or permutations and combinations in football pools, is no less statistical for being popular and widespread, yet when the psychologist attempts to employ statistical methods in relation to serious subjects he encounters the usual obscurantist notion that you can prove anything with statistics In a sense, this is true You can 'prove' anything with statistics, but only to a person who is completely ignorant of elementary statistical notions"—H J EYSENCK, *Sense and Nonsense in Psychology* Harmondsworth, 1957, p 17

SARCOSPORES AND TOXOPLASM SEROLOGY

AN INVESTIGATION OF THEIR ALLEGED CROSS-REACTION

I A B CATHIE
M D Lond, M R C P
CLINICAL PATHOLOGIST

G W CECIL
F I M L T
CHIEF TECHNICIAN

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON

EXPERIMENTAL evidence (Cathie 1957) contradicting various attacks on the specificity of the dye test and the complement fixation test for toxoplasmosis seems to show that complement fixing antigens made from animal tissues give non specific results, that much of the experimental work done on animals was not applicable to man, and that a substance contained in some sheep and other animal sera and capable of modifying toxoplasms was not the dye test antibody because it was heat labile This observation led to the recommendation that sera to be used in the dye test should be previously inactivated to avoid misleading results due to this toxoplasm hostile factor

The Sabin and Feldman (1948) dye test for toxoplasmosis consists in showing that an antibody can modify normal toxoplasms so that, on the addition of methylene blue, they do not stain For this interaction a heat-labile substance, known as accessory factor, present in normal human serum is essential

Awad (1954) claimed that sarcospores of *Sarcocystis tenella* could be used interchangeably with toxoplasms in the dye test He found that all of 6 sheep and each of 2 rabbits infected with sarcocystis gave a positive dye test with sarcospores, all of 3 guineapigs infected with toxoplasms gave a positive dye test with sarcospores, and 3 human, 3 sheep, and 2 rabbit "control" sera were negative He found further that human sera giving a positive dye test for toxoplasmosis gave the same reaction to similar titres when sarcospores were used instead of toxoplasms

The many technical considerations involved in setting up a dye test with sarcospores are not dealt with by Awad The bugbear of all dye tests, both in this country and abroad (J K Frenkel, personal communication), is the necessity for adequate supplies of antibody negative suspending serum, and the provision of this in a form suitable for using sarcospores was not discussed by Awad

We report here an attempt to repeat Awad's work

Material and Methods

Sarcospores were obtained by the kind cooperation of Mr H T Yelland, of the Islington Cattle Market, who provided us with fresh sheep gullets containing visible parasitic lesions Suspensions of sarcospores were prepared from these by the method described by Awad (1954) Since Awad did not indicate to what age sarcospores could be used, tests were made with them as soon as a suspension had been prepared from fresh gullets and up to a month later

Sarcocystis complement fixing antigen was kindly supplied by Prof P C C Garnham

Suspending serum known to be free from toxoplasm dye test antibody was obtained from the same donor who has supplied us with serum for routine dye tests for the past seven years Dye test techniques were those described by Cathie and Dudgeon (1953) and Cathie and Cecil (1954)

Human sera containing different antibody content for toxoplasms were chosen from those sent by other laboratories for routine testing

Results

Dye tests with 23 human sera of known toxoplasm-antibody content were set up with toxoplasms and sarcospores, the sarcospores being used on the day of receipt or as fresh as possible About a third of the sera contained toxoplasm antibody, but all 23 gave a positive dye test with the sarcospores (table I) 93 other human sera were therefore investigated as they came to hand, and all were found to have antibodies which modified the sarcospores used in this test

TABLE I—RESULTS OF TESTS WITH HUMAN SERA

Human sera nos	Results			
	Toxoplasm dye test with suspending serum in dilution			Sarcocystis dye test with no suspending serum in dilution 1/4
	1/4	1/8	1/16	
1	−	−	−	−
2–7	−	−	−	−
8	−	−	+	−
9	−	−	−	+
10–11	−	−	+	−
12	−	−	−	+
13–14	+	−	−	−
15	−	−	+	−
16–18	−	−	−	−
19–20	−	+	−	−
21–23	−	−	−	+

On repeating the test with sarcospores and the same 23 human sera after inactivation at 56°C for 30 minutes, all the tests had become negative, the sarcospores not being modified but staining readily with methylene-blue

Awad (1954) said he suspended the sarcospores in either saline solution or "normal human serum," and his dilutions were made in "normal human serum" All the 116 normal human sera that we have tested contained sarcospore-hostile substances which render the dye test impossible In table I, where human sera were put up with sarcospores, the sera provided their own accessory factor if such were necessary When these sera gave no modification after inactivation, it may have been either because the sarcospore-hostile factor had been removed or because accessory factor had been destroyed, but, since all the sera not inactivated contained this sarcospore-hostile factor, it was impossible to add a secondary source of accessory factor to show precisely what factor or factors, had been inactivated

TABLE II—RESULTS OF TESTS WITH GUINEAPIG SERA

Guineapig serum immunised with sarcocystis C F T antigen	Results of dye test made with sarcospores and toxoplasmosis negative suspending serum in dilution							
	1/4	1/8	1/16	1/32	1/64	1/128	1/256	1/512
1 Guineapig serum unheated all diluents saline	+	−	+	−	+	−	−	−
2 Guineapig serum unheated suspending serum unheated	−	−	−	−	−	−	−	+
3 Guineapig serum unheated suspending serum heated	+	+	+	−	−	−	−	−
4 Guineapig serum heated all diluents saline	−	−	−	−	−	−	−	−
5 Guineapig serum heated suspending serum unheated	+	+	−	−	−		−	−
6 Guineapig serum heated suspending serum heated	−	−	−	−	−	−	−	−

Sera which contained dye-test antibody for toxoplasms and, after inactivation, did not modify sarcospores any longer were shown to have their dye-test antibody for toxoplasms still complete, thus showing the essential difference between this antibody and whatever in the non-inactivated state can modify sarcospores

Any attempt to remove this sarcospore-hostile factor differentially by inactivation would defeat its own ends because, unfortunately, accessory factor is heat-labile, and a dye test cannot be made if all the sera taking part in the test have been inactivated

Table II illustrates experiments which confirm this point In experiment 1 a guineapig was immunised with sarcocystis complement-fixing antigen, and its complement-fixation test became positive A false dye test with sarcospores on this guineapig's serum was positive at a dilution of 1 128 but negative at 1 256, this must have been a false test because the doubling dilutions were made in saline solution, and at a dilution of 1 256 there cannot possibly have been enough accessory factor present for this to be a true dye test (we have to make all our dilutions in normal human sera to make the toxoplasm dye test work satisfactorily) The same guineapig serum, put up as a formal dye test using our toxoplasm accessory-factor serum was positive at all dilutions, showing once again that "normal human serum" cannot be used for a dye test with sarcospores

The guineapig serum after inactivation at 56°C for 30 minutes fell in titre with sarcospores in saline solution from 1 128 to 1 4 If this fall was due to the destruction of accessory factor in the guineapig serum, the test should have become negative The result is far more likely to be due to the destruction of most of some sarcospore hostile factor That a similar factor is present in the donor of our accessory-factor serum for toxoplasmosis is shown by experiment 3 in table II, in which the guineapig's titre was still 1 128 when our suspending serum after inactivation was used for the diluent Experiments 5 and 6 of table II confirm that our normal human suspending serum cannot be used for a dye test with sarcospores

Age of Sarcospores

As we had no information about the age to which a sarcospore suspension can be used, the experiment was repeated which showed that inactivated sera had lost the ability to modify fresh sarcospores The sarcospores, on the second occasion being 30 days old, were still all modified by human sera On this occasion, however, inactivation did not affect the sarcospore hostile factor, all of 22 sera modifying the sarcospores after heating in the same way as they all had done before heating

The meaning of this finding is not clear As far as can be seen, the only variable factor is the age of the sarco spore suspension, the sarcospores, at the age of 30 days, had altered so that they became modified with inactivated sera, a property they did not have when fresh We had thought, on possibly slender grounds, that the dye test with toxoplasms was a vital phenomenon, but it does not seem likely that this alteration in the capacity of sarcospores, after 30 days in the refrigerator, for being modified by human sera can be connected with any vital capacity of the sarcospores particularly as, when fresh, they do not have this property of modification by inactivated sera

Sheep Sera and Sarcosporidiosis

Of 10 sheep sera collected at random from the abattoir 6 contained complement fixing antibodies for sarco sporidiosis and 4 did not All the sera gave an apparent dye test with sarcospores in that the sera modified them, but after inactivation these 10 sheep sera no longer modified fresh sarcospores This result indicates that sheep sera contain a heat labile substance similar to that in human sera capable of modifying sarcospores, but this substance shows no conformity with the complement-fixing antibody, and, if the latter can be taken to indicate infection with sarcocystis, the sarcospore hostile factor, giving an apparent dye test in 100% of all the sera that we have tested, does not appear to diagnose anything

Comment

We feel that Awad's (1954) claim that sarcospores can be used interchangeably for the diagnosis of both toxoplasmosis and sarcosporidiosis is refuted, because all of 116 human sera and all of 10 sheep sera contained a sarcospore hostile factor That this can be removed by inactivation at 56°C for 30 minutes would not help in establishing a dye test with sarcospores, because accessory factor would inevitably be concurrently removed, and without this the dye test cannot be made Also the dye test antibody for toxoplasmosis is heat stable Secondly, we have encountered this perplexing finding that fresh sarcospores are not modified by inactivated sera, whereas old sarcospores are, unless and until this phenomenon can be explained rationally and perhaps exploited, there seems to be no point in further concern with sarcospores in the laboratory diagnosis of toxoplasmosis Even if this were to be worked out, there is still our total inability to find either a negative control or, indeed, a negative test

On repeating Awad's (1954) work we were unable to obtain results at all comparable with his Our technique of the dye test does not differ materially from that originally described by Sabin and Feldman (1948) and used by Awad and has given us consistent results over eight years The only difference between the two dye test techniques used in our experiments was the substitution of sarcospores for toxoplasms Although we have meticulously followed such technical details as are mentioned by Awad, we have not found it possible to use sarcospores in the diagnosis of anything, and it seems probable that Awad did not mention some point of technical detail our omission of which has led to these discordant results

The suggestion that there is some common antigenic relationship between sarcocystis and toxoplasms is not upheld by our findings, in fact, the ability to remove the sarcospore hostile factor and to retain the toxoplasm dye test antibody, together with the apparent specificity of the toxoplasm dye test antibody for toxoplasmosis, indicates that these are two different substances It is a pity that we could not make this test work, because, as Awad points out, sarcospores are much bigger and more readily visible than toxoplasms, and if we had been able to use them we would gladly have substituted sarcospores for toxoplasms in the dye test for toxoplasmosis

Summary

Evidence is presented that human and sheep sera contain a substance capable of modifying the spores of *Sarcocystis tenella* so that they do not stain with methylene blue

This substance was present in all of 116 human and all of 10 sheep sera

Sarcospores therefore cannot be used to demonstrate the presence of dye-test antibodies for toxoplasmosis or sarcosporidiosis

RESULTS OF RADIOTHERAPY IN OSTEO-ARTHRITIS OF THE HIP

A H G MURLEY
M B Lond, F R C S
FORMERLY ORTHOPÆDIC REGISTRAR,
ST BARTHOLOMEW'S HOSPITAL, LONDON

OSTEO-ARTHRITIS has been treated by radiotherapy for over fifty years, but its mode of action and value are by no means agreed (Tillis 1944)

Langer (1933) attributed relief of pain to the effect of radiation on non myelinated nerve endings, with consequent hyperæmia and improved metabolism

Hill (1952) supposed that diminished sensitivity of nerve endings contributed, with hyperæmia, to the relief of pain

On the other hand, Kaplan (1945) thought that the blood supply was reduced and that diminished inflammatory response relieved pain by reducing distension of nerve sheaths

Harrison et al (1953) confirmed hyperæmia of the osteo arthritic femoral head and attributed much of the joint pain to attempts at repair rather than degenerative changes

Ewing (1926) said that diminished vascularity was the first of the radiological effects on bone, but these cannot be divorced from the effect on soft tissues, such as the capsular and muscle attachments

Kahlmeter (1938) found these tissues the most sensitive to irradiation in all forms of degenerative joint disease

The purpose of the present investigation was to determine the efficacy of radiotherapy in relieving the pain from osteo-arthritis of one large joint By far the most important symptom to the patient is pain, and this is notoriously difficult to assess The symptoms of osteo arthritis tend to fluctuate irrespective of treatment, and there are no objective criteria Moreover, patients, reluctant to disappoint those who have been trying hard to relieve their pain, often colour their replies accordingly

Joly and Hanoune (1952) reported that pain was at least partly relieved in 66 of 295 patients treated by radiotherapy Some of these patients had additional radiotherapy to the lumbar spine Joly and Hanoune regard the most effective hip dosage as *1000–2000r* in six doses in one week from a 150 kV apparatus

It was felt that a more accurate assessment would be achieved by eliminating the personal factor of an interview and by sending a simple questionnaire to patients at least a year after treatment

After an initial explanatory note, the following questions were asked

> After your X ray treatment was your pain better, worse, or unchanged ?
>
> If the pain was altered, how long after treatment started did you first notice the alteration ?
>
> If your pain was altered, for how long did the alteration last ?
>
> Did you notice any other effects of the treatment ?

All the patients in this investigation had received treatment by various physiotherapeutic methods, with only partial relief or none at all All the patients were either moderately or severely disabled, 14 of them were subsequently subjected to major surgery when radiotherapy failed to give satisfactory relief of symptoms The length of follow up varied from eighteen months to seven years, and possibly further patients will require surgery later

Results

Of 62 patients treated 59 were traced 29 men average age 59, and 33 women, average age 58, when treatment began 2 of these patients had later died, each about two years after treatment and of unrelated causes, both had moderate improvement, which was maintained until death Of the remaining 57 patients 11, with twelve treated hips, had subjective improvement, but this lasted for more than a year in only 5 patients Improvement was considerable in 3, moderate in 6, and slight in 2 The average duration of symptoms before treatment was six years

Ill effects of treatment were few 2 patients complained of malaise and abnormal tiredness, 1 woman, aged 46, had persistent amenorrhœa after treatment—she was the only patient who found the pain increased by treatment

43 patients could not detect any appreciable effect of radiotherapy

Conclusions

Radiotherapy may be given in a dose of 1200–1500r to a hip joint in 6–10 fractions in two weeks with few complications due to treatment

Less than a quarter of 57 patients with osteo-arthritis of the hip derived subjective benefit from irradiation of the hip joint In only 5 patients did benefit last longer than a year

I wish to thank Mr S L Higgs, Mr H Jackson Burrows, Mr. W D Coltart, Mr I G Williams, and Dr A E Jones for permission to publish this paper

IT is common knowledge that a green or blue tinge to the sputum may be produced by *Pseudomonas pyocyanea* It is far from common knowledge, however, that a red sputum, indistinguishable from a bloodstained specimen, may be produced by *Chromobacterium prodigiosum* Ignorance of this fact, even among chest physicians, is easily explained, for up to 1955 it has been possible to trace only two cases of natural infection of the respiratory tract with this organism

The classification of the chromobacterium group of organisms has always been somewhat difficult They are small gram negative aerobic rods producing a pigment which may be yellow, violet, or red *C prodigiosum* may vary morphologically from a coccobacillus to a rod The group is usually found in water and soil and may contaminate food (Wilson and Miles 1955)

Most infections in man with *C prodigiosum* have involved the genito-urinary tract (Wheat et al 1951), but cases have been described of fatal septicæmia (Patterson et al 1952), bacterial endocarditis (Hawe and Hughes 1954), and meningitis (Aronson and Alderman 1943) The type of case described below has rarely been published

Case-report

On July 19 1956 a man aged 59 was admitted to hospital because of a chronic cough and copious purulent sputum, these symptoms had been present since an attack of pneumonia five years previously His temperature and pulse rate were normal and a general examination showed little of note except finger clubbing generalised emphysema and bilateral basal crepitations in the lungs Naked eye examination of the sputum however showed it to contain pus and it appeared to be frequently bloodstained A blood count showed red cells 4 620 000 per c mm., Hb 56% colour index 0 6, and white cells 5000 per c mm Bronchiectasis was diagnosed and confirmed by bronchography, which demonstrated "cystic" bronchiectasis of both lower lobes, the middle lobe and lingula, and the anterior segments of the upper lobes Bronchoscopy revealed pus in both lower-lobe bronchi which were also appreciably distorted Specimens of sputum did not supply any microscopical evidence of blood, and it was subsequently noted that the red colour of the sputum developed only on standing Cultures were reported consistently as growing *C prodigiosum* and *Proteus mirabilis*, the former organism produced luxuriant orange-red colonies In spite of treatment with penicillin, streptomycin, terramycin, aureomycin, and chloramphenicol, the patient continued to produce cultures of this organism These cultures were resistant to all in-vitro drug sensitivity tests except as regards chloramphenicol and neomycin However, the patient's general condition was much improved—possibly owing to effective physiotherapy—and he was discharged home on Aug 28, 1956

Bacteriology —The organism consisted of short gram negative rods (about 1 0–1 5×0 7 µ, with occasional rods up to 4 µ long), motile by a few peritrichate flagella It formed round convex colonies with a smooth shiny surface on agar, and grew better at 37°C than at 25°C It produced deep orange red pigment on agar at 25°C but little or no pigment at 37°C The pigment was insoluble in water but soluble in chloroform and in alcohol An alcoholic solution of pigment turned pink, then violet, on the addition of acid, and yellow on the addition of alkali The organism grew anaerobically without producing pigment It produced dense turbidity in broth at 25°C, with a pink ring growth and a reddish deposit It produced clot in litmus milk, followed by liquefaction Saccate liquefaction was caused by a gelatin stab It produced acid and a little gas from glucose, mannitol, maltose, sucrose, and salicin at 37°C, but none from dulcitol and lactose Glucose was attacked fermentatively (Hugh and Leifson 1953) Indole –, M.R –, V P +, Koser's citrate +, nitrates reduced, NH3 production +, catalase +, methylene blue reduced urea – at 24 hr (Christensen 1946), H_2S + The description of this organism closely resembles that given for *C prodigiosum* by Wilson and Miles (1955) A culture has been deposited with the National Collection of Type Cultures (no 9940)

Discussion

There seems to be little doubt, from a review of published reports, that this organism can produce either a mild chronic illness or a fulminating fatal one, usually a septicæmia It is, of course, very difficult to assess the pathogenicity of the organism in the present case It is of interest that the sputum remained persistently contaminated in spite of heavy and varied antibiotic therapy These findings are in keeping with the experience of most other workers Hawe and Hughes (1954) thought that either chloramphenicol or neomycin might offer the best chance of successful treatment The in-vitro sensitivity tests tend to bear out this view

Aitoff et al (1936) have described a case in which a pure culture of *C prodigiosum* was obtained from a patient with lobar pneumonia Woodward and Clarke (1913) described a case quite similar to the one described above, the patient, who apparently had bronchiectasis, complained repeatedly of bloodstained sputum, whereas it really contained no red corpuscles but grew profuse colonies of *C prodigiosum* Sometimes the red colour of the sputum occurs only on standing, the degree of pigmentation depending on the oxygen supply

We wish to thank Dr M T Parker and Dr J D Abbott for investigating and reporting on the bacteriological aspects of the case

dye test with sarcospores in that the sera modified them, but after inactivation these 10 sheep sera no longer modified fresh sarcospores This result indicates that sheep sera contain a heat labile substance similar to that in human sera capable of modifying sarcospores, but this substance shows no conformity with the complement-fixing antibody, and, if the latter can be taken to indicate infection with sarcocystis, the sarcospore hostile factor, giving an apparent dye test in 100% of all the sera that we have tested, does not appear to diagnose anything

Comment

We feel that Awad's (1954) claim that sarcospores can be used interchangeably for the diagnosis of both toxoplasmosis and sarcosporidiosis is refuted, because all of 116 human sera and all of 10 sheep sera contained a sarcospore hostile factor That this can be removed by inactivation at 56°C for 30 minutes would not help in establishing a dye test with sarcospores, because accessory factor would inevitably be concurrently removed, and without this the dye test cannot be made Also, the dye test antibody for toxoplasmosis is heat-stable Secondly, we have encountered this perplexing finding that fresh sarcospores are not modified by inactivated sera, whereas old sarcospores are, unless and until this phenomenon can be explained rationally and perhaps exploited, there seems to be no point in further concern with sarcospores in the laboratory diagnosis of toxoplasmosis Even if this were to be worked out, there is still our total inability to find either a negative control or, indeed, a negative test

On repeating Awad's (1954) work we were unable to obtain results at all comparable with his Our technique of the dye test does not differ materially from that originally described by Sabin and Feldman (1948) and used by Awad and has given us consistent results over eight years The only difference between the two dye test techniques used in our experiments was the substitution of sarcospores for toxoplasms Although we have meticulously followed such technical details as are mentioned by Awad, we have not found it possible to use sarcospores in the diagnosis of anything, and it seems probable that Awad did not mention some point of technical detail our omission of which has led to these discordant results

The suggestion that there is some common antigenic relationship between sarcocystis and toxoplasms is not upheld by our findings, in fact, the ability to remove the sarcospore-hostile factor and to retain the toxoplasm dye test antibody, together with the apparent specificity of the toxoplasm dye test antibody for toxoplasmosis, indicates that these are two different substances It is a pity that we could not make this test work, because, as Awad points out, sarcospores are much bigger and more readily visible than toxoplasms, and if we had been able to use them we would gladly have substituted sarcospores for toxoplasms in the dye test for toxoplasmosis

Summary

Evidence is presented that human and sheep sera contain a substance capable of modifying the spores of *Sarcocystis tenella* so that they do not stain with methylene blue

This substance was present in all of 116 human and all of 10 sheep sera

Sarcospores therefore cannot be used to demonstrate the presence of dye test antibodies for toxoplasmosis or sarcosporidiosis

RESULTS OF RADIOTHERAPY IN OSTEO-ARTHRITIS OF THE HIP

A H G MURLEY
M B Lond, F R C S
FORMERLY ORTHOPÆDIC REGISTRAR,
ST BARTHOLOMEW'S HOSPITAL, LONDON

OSTEO ARTHRITIS has been treated by radiotherapy for over fifty years, but its mode of action and value are by no means agreed (Tillis 1944)

Langer (1933) attributed relief of pain to the effect of radiation on non myelinated nerve endings, with consequent hyperæmia and improved metabolism

Hill (1952) supposed that diminished sensitivity of nerve endings contributed, with hyperæmia, to the relief of pain

On the other hand, Kaplan (1945) thought that the blood supply was reduced and that diminished inflammatory response relieved pain by reducing distension of nerve sheaths

Harrison et al (1953) confirmed hyperæmia of the osteo arthritic femoral head and attributed much of the joint pain to attempts at repair rather than degenerative changes

Ewing (1926) said that diminished vascularity was the first of the radiological effects on bone, but these cannot be divorced from the effect on soft tissues, such as the capsular and muscle attachments

Kahlmeter (1938) found these tissues the most sensitive to irradiation in all forms of degenerative joint disease

The purpose of the present investigation was to determine the efficacy of radiotherapy in relieving the pain from osteo arthritis of one large joint By far the most important symptom to the patient is pain, and this is notoriously difficult to assess The symptoms of osteo arthritis tend to fluctuate irrespective of treatment, and there are no objective criteria Moreover, patients, reluctant to disappoint those who have been trying hard to relieve their pain, often colour their replies accordingly

Joly and Hanoune (1952) reported that pain was at least partly relieved in 66 of 295 patients treated by radiotherapy Some of these patients had additional radiotherapy to the lumbar spine Joly and Hanoune regard the most effective hip dosage as 1000–2000r in six doses in one week from a 150 kV apparatus

It was felt that a more accurate assessment would be achieved by eliminating the personal factor of an interview and by sending a simple questionnaire to patients at least a year after treatment

After an initial explanatory note, the following questions were asked

After your X ray treatment was your pain better, worse, or unchanged ?

If the pain was altered, how long after treatment started did you first notice the alteration ?

If your pain was altered, for how long did the alteration last ?

Did you notice any other effects of the treatment ?

All the patients in this investigation had received treatment by various physiotherapeutic methods, with only partial relief or none at all All the patients were either moderately or severely disabled, 14 of them were subsequently subjected to major surgery when radiotherapy failed to give satisfactory relief of symptoms The length of follow up varied from eighteen months to seven years, and possibly further patients will require surgery later

Results

Of 62 patients treated 59 were traced 29 men, average age 59, and 33 women, average age 58, when treatment began 2 of these patients had later died, each about two years after treatment and of unrelated causes, both had moderate improvement, which was maintained until death Of the remaining 57 patients 11, with twelve treated hips, had subjective improvement, but this lasted for more than a year in only 5 patients Improvement was considerable in 3, moderate in 6, and slight in 2 The average duration of symptoms before treatment was six years

Ill effects of treatment were few - 2 patients complained of malaise and abnormal tiredness; 1 woman, aged 46, had persistent amenorrhœa after treatment—she was the only patient who found the pain increased by treatment

43 patients could not detect any appreciable effect of radiotherapy

Conclusions

Radiotherapy may be given in a dose of 1200–1500r to a hip joint in 6–10 fractions in two weeks with few complications due to treatment

Less than a quarter of 57 patients with osteo-arthritis of the hip derived subjective benefit from irradiation of the hip-joint In only 5 patients did benefit last longer than a year.

HÆMOLYTIC TRANSFUSION REACTION DUE TO ANTI-KELL

J H FRIEND
M D Lond , M R C P
CONSULTANT PHYSICIAN

C GILES
M D Manc , B Sc
CONSULTANT PATHOLOGIST
CITY GENERAL HOSPITAL, STOKE-ON-TRENT, STAFFS

W WEINER
M D Prague
DIRECTOR, REGIONAL BLOOD TRANSFUSION SERVICE, BIRMINGHAM

EMERGENCY blood-transfusions may later lead to "emergencies" of a different kind The following case illustrates one of the complications which may arise if the tests preceding this treatment are not carried out completely

Case-report

A married woman, aged 30, became pregnant for the second time in August, 1955 She had had no serious illnesses in the past and had certainly never received any blood transfusions or injections of blood Apart from one normal live birth there had been no other pregnancy On April 12, 1956, she attended the antenatal clinic for the first time, and intra uterine death was suspected A swelling in her neck was noted and diagnosed as tuberculous adenitis On April 15, in her 36th week of pregnancy, she was admitted to hospital with vaginal bleeding and abdominal pain Next morning a dead 20 week fœtus was born, and this was followed two hours later by a fairly severe postpartum hæmorrhage An urgent request for three pints of blood was received by the pathologist on duty The patient's blood-group was determined as group A rhesus negative Three pints of homologous blood was cross matched by the albumin method, being incubated for an hour at 37°C, and all three bottles were found to be compatible An indirect Coombs test was not done

Transfusion and Progress —Two pints was transfused immediately and given fairly quickly The third pint was given during the morning of April 16 The patient's general condition improved, but in the afternoon she was found to be jaundiced On April 17 she became anuric Since the usual Bull's regime was not tolerated, owing to constant vomiting, 5% glucose in water was given by mouth, followed by 40% glucose by intragastric drip When, by April 20, diuresis had not begun an intracaval drip (Russell et al 1954) was set up and 40% glucose administered Insulin was given in an attempt to stem the rising serum potassium level Diuresis started on April 24, when she passed 160 ml of urine, and the amount of urine increased during the following forty eight hours Infection of the surrounding skin made it necessary to remove the intracaval catheter on April 26 Next day the serum potassium level rose to 9 2 m eq per litre and reached 10 2 m eq per litre on April 28 By this time a massive diuresis had set in (4 litres in twenty four hours), and the serum-potassium level dropped to 5 0 m eq per litre on April 30 The blood urea level rose to 252 mg per 100 ml on the same day but declined rapidly thereafter Polyuria went on for another week, with the serum potassium dropping to 3 3 m eq per litre The patient's general condition improved, but persistent anæmia necessitated a further blood-transfusion She was well enough on May 23 to be discharged home, when her blood urea was normal and her hæmoglobin 9 3 g per 100 ml (63%)

Follow up —By June 11 her hæmoglobin had increased to 10 9 g per 100 ml (74%) and on Nov 15 it was 12 3 g per 100 ml (83%), and her blood urea was 19 mg per 100 ml

Biochemical and Serological Findings —The clinical diagnosis of hæmolytic transfusion reaction was confirmed by a positive Schumm's test and a bilirubin level of 14 mg per 100 ml on the evening of April 16 The patient's cells on this date gave a positive direct Coombs test Reinvestigation of the serology showed that her blood group had been correctly determined as group A rhesus negative, and the donors' blood groups were also found to be correct The cross match was now repeated with serum obtained from pre and post transfusion specimens, and again no incompatibility was found when the cells and the specimen were suspended in saline solution or in albumin, but two of the three pints of blood gave a strongly positive indirect Coombs test with the patient's serum A full investigation then showed that the antibody present in the patient's serum was anti Kell The two bottles which gave the positive indirect Coombs test with the patient's serum were Kell positive, whereas the third, which had given a negative indirect Coombs test, was Kell negative The blood group of the patient's husband was group O rhesus negative, Kell positive, and Fy (a)

Discussion

This patient was not regarded as a "dangerous recipient" (Tovey 1950), having had only one pregnancy in the past and no history of transfusion or injections of blood Nevertheless her serum contained a powerful anti-Kell antibody obviously produced by the stimulus of the pregnancies Whether the tuberculous adenitis enhanced antibody formation is a matter for conjecture Unfortunately the dead fœtus was not examined, and cord blood was not obtained Therefore it is unknown whether the Coombs test in the baby's cells was positive No doubt the severe transfusion reaction could have been avoided had a Coombs test been done when the blood was cross matched, but it was assumed that the case was too urgent to allow time for this test It is common experience that the albumin method will not show up all antibodies which may produce a severe transfusion reaction The performance of the indirect Coombs test therefore appears to be advisable in all women who have been pregnant or cannot give a precise history

This case again shows the value of the intracaval administration of hypertonic glucose in the treatment of anuria

Summary

A severe hæmolytic transfusion reaction was due to an anti-Kell and caused anuria An indirect Coombs test should be used more often than at present in cross matching blood for parous women

Our thanks are due to Mr H Burton for permission to publish this case

New Inventions

A NEW RECOVERY-ROOM TROLLEY

IN a recovery-room, the use of a standard hospital bed has many disadvantages It is space consuming where the space is often limited, it is cumbersome to move and tilt, and a fixed head makes laryngoscopy or bronchoscopy extremely difficult Moreover, it entails too frequent movement of the patient who is shocked or has had regional or hypotensive anæsthesia, in that he has to be moved from operating-table to trolley, thence to a recovery bed and later back to a trolley, and finally back to a bed again in the surgical ward These manœuvres require the close attention of several nurses and porters

To eliminate such difficulties, a recovery-room trolley has been designed incorporating features which allow the patient to remain on it from the time he leaves the theatre table, throughout his stay in the recovery room, to the time he returns to the ward Thus he has to be moved only twice

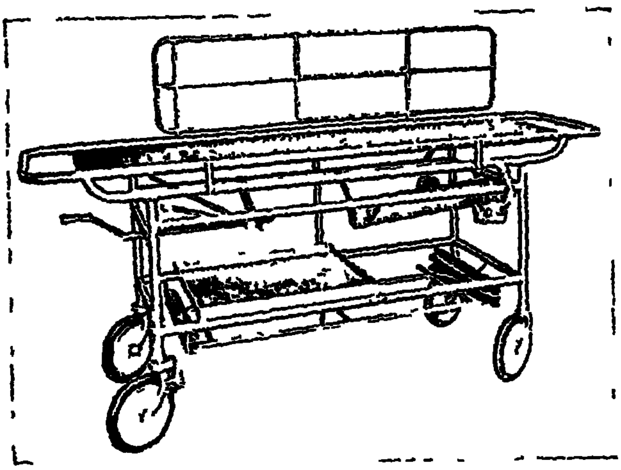
This trolley is basically similar to the standard hospital trolley It is, however, more sturdily built and has the following additional features

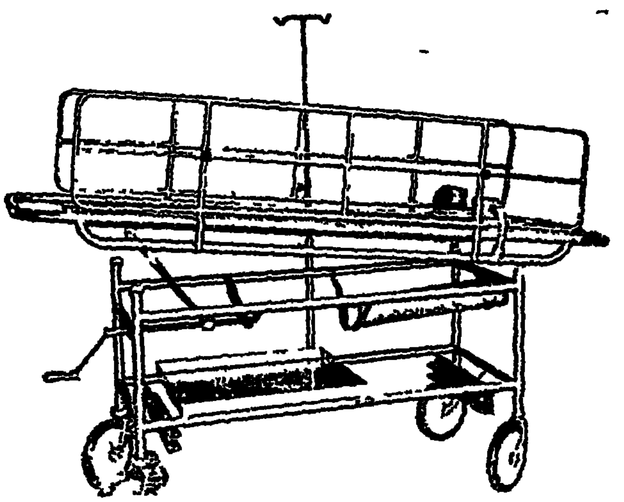
(1) Easily adjustable Trendelenburg tilt by means of a handle at the foot

(2) Adjustable self locking shoulder-rests.

(3) Detachable side rails with telescopic ends which stow away in a compartment beneath the trolley when not in use

(4) Adjustable drip stand attachment on either side of the trolley





(5) Container for oxygen cylinder beneath trolley

(6) Tray beneath trolley for case sheets, utensils, dressings, &c, brought from the ward

(7) Locking wheels (foot action)

(8) Thick 'Sorbo' rubber mattress

As the trolley stands just higher than a standard hospital bed, the patient who is on a draw-sheet can be lifted with a minimum of effort on to the ward bed when required Two of these trolleys have been in use in the recovery-room at the Royal Infirmary, Wigan, for some months and have proved so satisfactory that it is proposed to replace the remaining beds by more such trolleys soon

The trolley is manufactured by Messrs Siddall & Hilton, of Sowerby Bridge, Yorks, to whom considerable credit is due for their lively interest and cooperation in its production

Reviews of Books

The Pathogenesis of Coronary Occlusion

A D MORGAN, M A, M D, head of the morbid anatomy department and reader in pathology, Westminster Medical School, and consultant pathologist, Westminster Hospital, London, Oxford Blackwell Scientific Publications 1957 Pp 171 42s

SINCE ischæmic heart-disease is now responsible for the deaths of one fifth of the nation, and coronary atherosclerosis is present to a greater or lesser extent in every adult irrespective of age, a new monograph on the pathogenesis of coronary atheroma commands immediate attention

In the first half of this monograph, which is based on his M D thesis, Dr Morgan recounts briefly the early history of coronary atherosclerosis and reviews some of the theories of atherogenesis The historical section is very interesting, but the review lacks continuity and does not analyse or summarise adequately the views of previous workers Many will take issue with Dr Morgan's acceptance of atherosclerosis as an inevitable result of advancing age, with metabolic and endocrine disturbances as merely aggravating factors

In the second half, he recapitulates Duguid's views concerning the formation of atherosclerotic lesions During the past ten years most pathologists have come to realise that there is much evidence to support Duguid's observations that wisps of fibrin and frank arterial thrombi can be overgrown by endothelium and incorporated into the arterial wall Duguid maintains that many atherosclerotic lesions result from fibrin deposition and thrombosis, and that much of the fatty material in the atherosclerotic plaque is the result of degenerative changes Dr Morgan supports these observations with a detailed histological study of the coronary arteries from 40 patients with advanced coronary atherosclerosis, there are 174 photomicrographs and many of these are admirable, though only the frontispiece is in colour In Dr Morgan's view, intimal vascularisation is entirely the result of retraction and organisation of mural thrombi He believes that most of the cholesterol in the atherosclerotic plaque comes from the breakdown of red cells after mural thrombosis or capillary hæmorrhage into any existing plaque, and that it is possible to account for the presence of cholesterol in an atherosclerotic abscess without necessarily invoking a disorder of lipid metabolism

It would have been better if this monograph had been confined either to the excellent histological studies or expanded into a more comprehensive account of other views of the pathogenesis of coronary atherosclerosis, the present title is misleading, since the monograph is really an exposition of one view of atherogenesis Dr Morgan contends that the increasing incidence of thrombotic arterial occlusion is largely responsible for the greater frequency of ischæmic heart-disease He offers no evidence to support this hypothesis which, if the thrombogenic theory is correct, is difficult to reconcile with the fact that coronary atheroma has not increased during the past half century—a distinction which Dr Morgan himself emphasises

Dr Morgan is an enthusiastic advocate of Duguid's thrombogenic theory of the origin of atheromatous lesions, and it is instructive to read a review of this important approach to atherogenesis

Clinical Use of Radioisotopes

WILLIAM H BEIERWALTES, M D, coordinator, clinical radio isotope unit, University Hospital, Ann Arbor, PHILIP C JOHNSON, M D, chief, radio isotope unit, Veterans Administration Hospital, University of Oklahoma, ARTHUR J SOLARI, M S, radiation physicist for clinical radio isotope unit and Kresge research isotope unit, University Hospital, Ann Arbor Philadelphia and London W B Saunders 1957 Pp 456 80s 6d

WRITTEN primarily for the doctor taking part in the development of a clinical radio isotope unit, this book gives a particularly clear account of the principles underlying the use and measurement of radioactive materials, which should be very valuable to the medical graduate, who may have only a very superficial knowledge of nuclear physics

Most attention on the clinical side is rightly devoted to thyroid disorders and radioactive iodine, since this is undoubtedly the most important and popular use of an isotope in hospital Practical therapeutic aspects are well covered and for the most part the advantages and limitations of the new methods are adequately presented Little is said about the more fundamental aspects of the nature of the action of radiation on the thyroid cells, and recent work on carcinoma of the thyroid in children resulting from irradiation of the neck is not included In the chapter on diagnostic procedures no mention is made of the possible use of the short half-life ^{132}I, which considerably reduces the exposure of the gland to radiation

After turning to the use of other radioactive isotopes in clinical investigation and treatment, the book deals with the biological effects of radiation It concludes with the practical details of measuring radioactivity, and it even goes into the costs of investigations and the charges to be made to patients In an American book the regulations regarding the supply of isotopes do not, of course, apply to laboratories in this country

Doctors beginning work in a department using radioactive materials in clinical investigation will certainly find much to help them in this book

Medical Negligence

LORD NATHAN, P C, solicitor of the Supreme Court, chairman of the board of governors of Westminster Hospital, with the collaboration of ANTHONY R BARROWCLOUGH, B A, of the Inner Temple, barrister at law London Butterworth 1957 Pp 218 35*s*

THIS book collects much material hitherto available only in scattered reports It should interest lawyers and doctors alike, and is intelligible to both It demonstrates the care taken by the courts to reach decisions which not only do justice to plaintiffs but also protect a doctor's reputation when it deserves protection The standard of care is decided by the judge after weighing evidence given by other doctors; it is not a subjective standard of his own The frequent reiteration of the words "reasonable care" should comfort those who think that the courts demand the highest possible degree of skill and experience In the words of Lord Justice Scott, "the standard of care which the law requires is not insurance against accidental slips, it is such a degree of care as a normally qualified member of the profession may reasonably be expected to exercise in the actual circumstances of the case in question" Many examples are given of the "actual circumstances," but non-legal readers should remember that there is little law in these cases Each has been decided on its own facts, and few can safely be treated as precedents

The author suggests that all that solicitors need do to secure immunity from actions for professional negligence is to act on the opinion of counsel of reasonable competence It is perhaps worth noting, therefore, that solicitors are sometimes sued for negligence where there has never been any question of referring the case to counsel They are in no better a position than many a doctor Doctors have been found guilty of negligence because they did not refer the case to another doctor with special skill or knowledge, and the inference is that, had they done so, they themselves would have been immune

The book contains just over 200 pages, some of which are not strictly concerned with medical negligence, and many of the cases are not English but are from the Dominions and the United States Does this suggest that doctors in this country are not, after all, forever hovering on the edge of a legal abyss?

Troubles mentaux au cours des tumeurs intracraniennes

H HECAEN, médecin des hôpitaux psychiatriques, J DE AJURIAGUERRA, maître de recherche à l'Institut National d'Hygiène Paris Masson 1956 Pp 152 Fr 1500

THE partnership of Hecaen and Ajuriaguerra is becoming well known in modern French neurological literature Their contributions are always of value, and though this monograph is slighter than some of their work it contains useful information and a full review of previous literature

This study is based on 449 cases of cerebral tumour, in 229 of which mental changes were present The findings show that, though raised intracranial pressure (as judged by papillœdema) plays a part in producing general mental changes, this is not the whole answer When both the type of mental change and the site of the tumour are considered, the most striking fact is the relatively high incidence of a Korsakoff syndrome in lesions of the diencephalon and this supports the histological evidence in cases of alcoholic Korsakoff psychosis A more generalised "confusion dementia" syndrome commonly arises in frontal and fronto temporal tumours, whether or not papillœdema is present, whereas in occipital or posterior fossa tumours this syndrome is usually associated with papillœdema

In general, the book confirms the experience of those who see a lot of cerebral tumours, and it will be of particular value to psychiatrists who wish to define the rather amorphous group of organic dementia syndromes that they see

Atlas der gastroenterologischen Cytodiagnostik

N HENNING, director, and S WITTE, scientific assistant, Med Univ Klinik, Erlangen English translation by R O K SCHADE, M R C S Stuttgart Georg Thieme 1957 Pp 104 D M 38

THIS unpretentious atlas includes German and English versions in one cover, and the sound English translation makes the book unusually valuable to students of scientific German The text, less than 20 pages in each version, is disappointingly brief it includes, for instance, no statistics on the reliability of the methods described Professor Henning has been using his *Zellitupfsonde* (a gastric-tube-enclosed swab) in the diagnosis of gastric carcinoma since 1948, and exact figures of his success with it would have been very informative The black-and-white figures are many and good The gut is one of the newer and more difficult fields of exfoliative cytodiagnosis, and this is a useful introduction to it

---

Companion in Surgical Studies (2nd ed Edinburgh E & S Livingstone 1957 Pp 1302 84*s*)—A man seldom erects a monument to himself in his own time, but Prof Ian Aird has done so The first edition of his Companion had the quality of a "standard work" to which everyone turns for reference For the second edition he has an editorial committee of members of the staff of the Postgraduate Medical School of London and the Hammersmith Hospital to assist him, and together they have enlarged the book considerably Professor Aird has made no concession to those who deplored the absence of orthopædics from the first edition, he feels *he has been out of touch with the subject for too long* He should have stuck to his guns about illustrations too it seemed almost a merit of the first edition that it had none, now there is one plate and one diagram, neither of any importance, lost in the text, and they will hardly satisfy the critics who disliked a book without illustrations Nevertheless the second edition maintains the great reputation of its predecessor, and will indeed enhance it

Symptoms and Signs in Clinical Medicine (6th ed Bristol John Wright & Sons 1957 Pp 508 35*s*)—Dr E Noble Chamberlain's well known introduction to clinical medicine is now by way of becoming a minor classic In the new edition there have been changes, notably in the sections devoted to the cardiovascular and central nervous systems There are some new illustrations, including excellent coloured photographs Indeed, it seems a pity that any of the old coloured drawings were retained, for some of them now look very poor by comparison, and one or two are out of date and inaccurate We again commend this popular book to all students

Cleft Lip and Palate (2nd ed London Heinemann Medical Books 1957 Pp 187 42*s*)—The value of Mr W G Holdsworth's book has been much enhanced The chapters on operative repair include much new material and they now present a concise but comprehensive review of almost every surgical possibility A new chapter on embryology, contributed by Prof R J Harrison, is a masterly exposition of a complicated subject and goes far towards explaining some abnormalities which had hitherto been difficult to fit into the developmental pattern The second major addition, a chapter on orthodontic treatment by Mr M A Kettle, places in correct perspective the many claims made in this specialty, and enables the advantages of treatment to be properly evaluated Altogether, this new edition is vastly more informative than its predecessor

Shaw's Textbook of Gynæcology (7th ed London J & A Churchill 1956 Pp 704 32*s* 6*d*)—Wilfred Shaw's well known textbook was first published in 1936 Mr John Howkins has undertaken the revision for the new edition, and he is to be congratulated on maintaining the high standard and on preserving much of the original text while bringing the teaching up to date 116 new illustrations have been included and a number of important chapters have been largely rewritten

THE LANCET

LONDON SATURDAY, APRIL 20 1957

Vaccination and the Epidemiology of Poliomyelitis

RECENT studies have made clear the reasons for the striking differences in the incidence of paralytic poliomyelitis between countries with high and with low standards of living [1,2] In countries with a low standard of living people are usually infected by poliovirus in infancy or early childhood and thereafter they have a lifelong immunity to paralytic disease, whereas in countries with a higher standard of living and hygiene the first contact with poliovirus may be postponed to an age at which paralytic disease is more likely to result from infection. MELNICK et al [3] now report the results of a three-year study of selected populations in two American cities Specimens of sera and stools were collected repeatedly and were used to measure the infection-rates of different sections of the population in relation to their general socio-economic standards It was found that in each city members of the lower socio-economic group developed antibody early, and more than half of those aged 5–9 had antibody to any given type of poliovirus in higher socio-economic groups the same figures were not reached until early adult life These differences were clear on a gross district level, but, within each district, household size and state of sanitation were not important determinants of infection-rates The rates of virus isolation were more than three times greater in the lower socio-economic group and in certain cases it was possible to observe in retrospect silent subclinical epidemics in different districts There were no clinically apparent cases of poliomyelitis in the study-groups, but since clinical cases occurred elsewhere in both cities during the period of observation it was possible by assuming similar infection-rates to those of the study-groups to *compute crude* ratios of clinical to inapparent infections A rough calculation of this type suggested that the number of subclinical infections per clinical case varied from 32 to 406 clinical cases being associated most frequently with type-1 viruses Another interesting finding in this investigation [4] was that the presence of heterotypic antibodies did not reduce the incidence of subclinical infections among exposed persons On the other hand, the possession of homotypic antibody as a result of previous infection apparently prevented reinfection—a finding which falls in line with the work of others [5] A general conclusion from this work is that within relatively well-defined areas the age at which infection with polioviruses is acquired differs sharply and these differences can be clearly related to socio-economic rather than to climatic conditions A similar conclusion is reached by Dr BACKETT whose report we published last week.[6] BACKETT studied the poliovirus antibody pattern of nearly 300 children in Northern Ireland in relation to factors in their social background He found that there is more evidence of infection among children living in town than in country children, in lower than in upper social classes, in homes without constant hot water than those with and among children with many recreational contacts than those with few, and each of these factors seems to be independently associated with antibody patterns It is important that studies of this kind [7] should have been made now, since the picture may soon be greatly altered as the result of vaccination

What effects on the epidemiology of poliomyelitis may be expected to result from the continued use of formolised poliomyelitis vaccine ? A very thoughtful paper by Dr JOHN PAUL [8] raises important issues PAUL points out that so far the vaccine has produced acute immunity," which has reduced the incidence of paralytic poliomyelitis in children by 60–80% But we do not yet know whether vaccination of children by existing methods will protect them until they have reached the young adult age, at which infection is more likely to cause severe paralytic disease At the moment young adults in many populations are very vulnerable to paralytic disease In the U S A young parents are increasingly being infected by their children who have acquired virus at nursery-school and it will be remembered that many parents became infected when their children accidentally received live virus during the so-called Cutter incident in 1955 [9] Unlike natural infection vaccination does not prevent inapparent alimentary infections This has two implications When children are vaccinated first the young parents may for a time be more commonly exposed to the risk of paralytic infection as a result of inapparent infection by virulent virus in their children Secondly (as PAUL remarks) natural alimentary infection in a vaccinated child may still be necessary to maintain immunity throughout life Where and when these natural infections will occur may depend largely on the child s social circumstances Finally, PAUL raises the question whether reinfection should be left to pure chance or whether vaccination with live attenuated virus should be used as an adjunct to the vaccination with a killed virus Although the development of live virus vaccine has had a setback [10] this still seems a logical and hopeful line to pursue

Mechanisms of Periodic Paralysis

ONE of the things which makes medicine difficult (and interesting) is that apparently similar syndromes can be produced by several distinct mechanisms Familiar examples are megaloblastic anæmia and renal failure, and there is now a good deal of evidence that episodic paralysis, even in the absence of neurological disease, can be produced in different ways The first mechanism that was apparently established was the low plasma-potassium level giving rise to attacks of familial periodic paralysis, attacks can be terminated by giving potassium salts by mouth, and can be induced by giving adrenaline, or insulin and glucose, which lower the plasma-potassium[1] ALLOTT and MCARDLE[2] observed that the fall in plasma-potassium associated with the onset of an attack could not be accounted for by increased urinary excretion of potassium, and inferred that there must be a shift of potassium from the extracellular fluid into the cells Further balance studies have confirmed this finding[3] Last year ZIERLER and ANDRES[4] showed that there was a nocturnal shift of potassium into muscle-cells, which was five to ten times greater in patients with periodic paralysis than in healthy people The observed rate of entry into muscle of up to 1 m eq K per hr per kg of muscle would well account for the concurrent disappearance of potassium from the extracellular fluid (E C F), and it is tempting to relate the nocturnal entry of potassium into muscle to the tendency for attacks of periodic paralysis to start in the early hours

The association between hypokalæmia and paralytic attacks has now been observed not only in some patients with familial periodic paralysis but also in patients with abnormal losses of potassium, as in diabetic coma, the Fanconi syndrome,[5] and potassium-losing nephritis[6], yet evidence has also accumulated that hypokalæmia does not necessarily lead to paralysis and that familial episodic paralysis can occur without hypokalæmia Reviewing the relation between potassium and familial periodic paralysis, MCARDLE[7] draws attention to the common absence of paralysis at levels of plasma-potassium well below those associated with paralysis in the familial syndrome, and on the other hand to the remarkable family reported by TYLER et al[8] In this family episodic paralysis was inherited as a simple mendelian dominant, with 33 affected patients in seven generations, the paralytic episodes were not attended by any notable change in plasma-potassium, but biopsy showed vacuolation in the muscles The vacuoles did not contain fat or glycogen, and were presumed to contain "œdema fluid," although they lay within the muscle-fibres The relationship between potassium and paralysis is further complicated by the observations that hyperkalæmia may also be associated with paralysis,[9 10] and that hypokalæmia may at times be associated not with paralysis but with tetany[11] while in other patients the correction of hypokalæmia has unmasked hypocalcæmic tetany[12]

It is apparent from all this that no simple relationship exists between plasma-potassium and muscle paralysis, and speculative enterprise has tended to emigrate to the terra incognita within the cells A new lead in this direction is given by Professor CONN and his colleagues in their interesting observations set out in this issue on p 802 They outline their findings in two patients, unrelated to each other, who had "the familial type of periodic paralysis", one of them lived in the laboratory for eleven months of metabolic observation, and the other was studied for thirty days Both spontaneous and induced attacks of paralysis were preceded by massive retention of sodium and increased urinary excretion of aldosterone, recovery from the attack was attended by massive sodium diuresis Muscle biopsy during the attack showed a vacuolated lesion like that found in TYLER's family, but the two syndromes are not identical, for in CONN's 2 patients there was a profound fall in urinary and plasma potassium The sodium content of muscle was greatly increased, while the potassium content of muscle was normal, or a little diminished (The results now published do not indicate conclusively that the extra sodium in muscle is in fact intracellular, but a more detailed account is promised) When the patients were put on a low-sodium diet, it was no longer possible to induce attacks by glucose+insulin, or by fluorohydrocortisone On the basis of their findings, CONN et al suggest that "an abnormally high concentration of sodium within the muscle cell is partly responsible for the disturbance of muscle function" The cause of the observed intermittent aldosteronism is "not yet clear", and on the present results the possibility does not seem to be completely excluded that the increased aldosterone output is a secondary response to decreased E C F volume from a prior shift of fluid into cells along with potassium

This valuable new information raises further questions which can be readily studied Does artificial lowering of the plasma-potassium by insulin+glucose or by fluorohydrocortisone induce aldosteronism in healthy people, and if so how is this related to the stimulation of aldosterone output by a high potassium intake[? 13] If the aldosterone change is "primary," why is the sodium retention not accompanied by massive loss of potassium in the urine, as in sustained primary aldosteronism[? 14] If the intracellular vacuoles do contain sodium salts, by what mechanism are they sequestrated within the cell ? What part, if any, do the diurnal variations observed by ZIERLER and ANDRES play ? As MCARDLE[7] points out, quite a small primary change in extracellular potassium level may trigger off a chloride shift which will lead to further drastic lowering of external potassium, and it is notable that in 1 of the 2 patients studied by DANOWSKI et al[3] there was a negative external balance of potassium before the attack

From the practical point of view, perhaps the most interesting observation was that on a sodium intake

of 8 m eq a day there were no spontaneous attacks, nor could attacks be induced The efficacy of a low-sodium diet may indeed be partly due to concurrent potassium retention, for BARTTER[15] has suggested that minimal excretion of sodium may depress potassium secretion through lack of sodium ion available for exchange The diet used by CONN et al in their studies is considerably more restricted than the conventional low-salt diet. it would therefore be of great interest to find out whether an ordinary low-salt diet would prevent spontaneous attacks, or whether this would have to be supplemented by mercurial or other diuretic agents In some patients such a regime might have advantages over regular potassium supplements, which are not very palatable We would certainly agree with CONN that adrenalectomy is not indicated in the management of periodic paralysis

Resistant Tubercle Bacilli

THE possibility that drug-resistant tubercle bacilli might spread among the population was recognised when streptomycin was first used more than ten years ago Instances of such spread have now been reported in the U S A[16–19] France,[20–22] and Great Britain[23–25] Studies in the U S A suggested that resistant bacilli might account for about 1–2% of newly diagnosed infectious cases in that country[26 27], but the information was incomplete Accordingly, warnings about the dangers to the public health of indiscriminate and irrational chemotherapy of tuberculosis have been based on a-priori arguments. The tuberculosis research unit of the Medical Research Council with the coöperation of many chest physicians, has now remedied this defect Fox et al[28] describe a survey of the drug-sensitivity of cultures of tubercle bacilli isolated from newly discovered patients in Great Britain between June 1955 and March, 1956

> The bacteriological and statistical methods were designed to detect all strains which were at all resistant and to distinguish these from strains that were actually sensitive but were apparently resistant as a result of experimental variations in the sensitivity tests MITCHISON and SELKON[29] in a separate report on the bacteriological aspects of the survey, show that their estimates of the prevalence of strains resistant to streptomycin and *p*-aminosalicylic acid (P A S), if incorrect, were likely to be too low and that their estimate of isoniazid resistance may have been too high

A representative sample of eighty chest clinics was selected by a random process 1404 sputum specimens from the same number of newly diagnosed and untreated patients were cultured at a central laboratory From these specimens 974 positive cultures were obtained and 50 (5 1%) were resistant to one or more of the three commonly used drugs 44 (4 5%) being cultures of *Mycobacterium tuberculosis* and 6 (0 6%) cultures of atypical mycobacteria Of the 44 resistant cultures of *M tuberculosis*, 22 (2 3%) were resistant to streptomycin, 21 (2 2%) to P A S, and 7 (0 7%) to isoniazid, 5 were resistant to more than one drug In many instances the cultures were only slightly resistant, 19 of the 22 strains resistant to streptomycin having resistance ratios of no more than 16 But 3 strains were highly resistant to streptomycin 11 to P A S, and 5 to isoniazid 3 of the 7 strains resistant to P A S were of bovine type and may therefore, have been naturally resistant[30]

At present probably 1 in every 20 newly diagnosed infectious patients in this country has resistant tubercle bacilli in the sputum The prevalence varies with the age of the patient The highest proportion of resistant cultures was obtained from young women nearly 10% of the women aged 15–34 were infected with resistant bacilli—an alarmingly high proportion On the other hand, only 3% of the men in this age-group had resistant cultures The reasons for this unexpected difference between the sexes is unknown In those older than 34 there was little difference—4 9% in women compared with 4 1% in men The prevalence also varied with the part of the country in which the patients lived, the rate being 8 3% in Scotland and 8 2% in the Liverpool area but only 2 5% in the Birmingham area and 1 6% in Wales But the numbers of resistant strains from each area were small, and these differences may only have been chance fluctuations

FOX and his colleagues also investigated the possible sources of infection of the 44 patients with primarily resistant cultures and compared their contact histories with those of 44 matched patients with sensitive strains 47 contacts of the patients with resistant bacilli had been diagnosed as tuberculous since 1945, compared with only 16 contacts of the group with sensitive bacilli Moreover for each drug separately more of the resistant than of the sensitive group were known to have been in contact with patients treated with that drug—13 against 6 for streptomycin, 12 against 3 for P A S, and 3 against 0 for isoniazid Definite evidence of contact with organisms known to be resistant was obtained from 10 of the 44 patients infected with resistant strains, but no such contact was found within the sensitive group In at least half the patients infected with drug-resistant organisms the searching inquiry for contacts revealed nothing to arouse the clinician s suspicion that he might be dealing with a patient infected with resistant bacilli

Some of the implications of this important piece of epidemiological research are clear For the sake of the patient and the community all chemotherapy should be planned so that the risk of resistance is kept as small as possible Probably many of the primarily resistant strains in this survey arose through treatment that would by present standards be judged inadequate and unsafe It should now be very rare for a patient to remain infectious after chemotherapy[31 32] It has been suggested that treatment is less effective in older people [33], but this is unproved and it seems improbable (The current M R C trial of long-continued chemotherapy should answer some of the questions about the response to treatment of this important group of patients) The fact that almost a quarter of the patients infected with primarily resistant tubercle bacilli had been in contact with others known to be expectorating resistant bacilli suggests that preventive measures are not applied as efficiently as they might be The well-known, but not always well applied, preventive measures that are necessary in all infectious cases should be imposed with particular vigour when a patient remains infectious after chemotherapy Sensitivity tests on all pre-treatment cultures are desirable, but not always practicable In most cases in this country it is still possible to give effective treatment without such tests, but if the tests can be done the treatment can be more rational, more patients can be effectively treated, and the occasional discovery of primary resistant cultures will remind the physician of this danger There is much to be said for starting treatment with all three drugs simultaneously in newly diagnosed patients if this is practicable and if the risk of vestibular disturbance after daily injections of streptomycin in the older patient is accepted, and if pre treatment sensitivity tests can be done the results will indicate the most suitable combination of two drugs for further treatment

Annotations

THE BUDGET AND MEDICAL REMUNERATION

IN his Budget speech last week the Chancellor of the Exchequer declared that one of his aims was to increase the incentive to further effort by those earning over £2000 a year, and his proposals provide substantial relief for many in this group Thus a man earning £3000 a year who is married and is educating three children aged 11–16 will have his tax reduced from £906 to £732 The difference of £174 represents a tax-free gain of about 6% of the gross income, which is almost comparable to the taxable 10% lately added to the salaries of junior hospital staff as an interim measure [1]

The *Economist* [2] suggests that, with a view to ending the dispute over doctor's pay, the Government should fix the maximum sum that they are at the moment prepared to offer by way of " interim adjustment " and offer to negotiate with the medical leaders on its distribution We should greatly welcome such arrangement If the profession's negotiators found themselves at such a meeting their first thought would no doubt be for those who have not shared in the 10% increase for junior hospital staff and will benefit little if at all by the Budget proposals We have in mind particularly senior hospital medical officers and family doctors with small practices

HAZARDS OF EPOXIDE RESINS

IN the past few years a new group of synthetic materials, the ethoxyline or epoxide resins, has come into extensive use in industry, chiefly in the manufacture of electrical equipment, car bodies, and aircraft Most of these resins are aliphatic aromatic polyethers containing hydroxyl and terminal epoxy groups When they are mixed with highly reactive hardeners, which are usually polyamines, they are transformed at room-temperature into solid infusible substances Manufacturers of resins and hardeners are well aware of the hazards involved, but the introduction of these substances into works unfamiliar with chemical processes has resulted in many instances of toxicity

Pletscher et al [3] reported that, of 20 workmen handling one of these resins, 6 had severe eczema and 8 temporary skin irritation On patch testing, 4 of the affected 14 were hypersensitive to the resin, 2 to the hardener, and 3 to both substances The 6 unaffected men were not hypersensitive According to Grandjean,[4] the eruption associated with these resins has an initial phase, lasting from a week to several months, during which itchy erythematous patches appear on the face and upper limbs In some people the reaction never proceeds beyond this stage, which may be due to primary irritation by the alkaline hardener or be an early manifestation of sensitisation to the resin In others, further contact leads to a very irritating papulovesicular eruption, and at this stage the patient has to stop work

Grandjean has formulated protective measures The worker should be taught to avoid spilling the resin or hardener or contaminating door-handles or pencils Good ventilation and local exhaust equipment are desirable Workers should wear gloves, plastic cuffs, and white overalls, and their faces may be protected by barrier creams

VITAMIN A AND THE CEREBROSPINAL FLUID

DEFICIENCY of vitamin A is usually believed to give rise to nothing more severe than impairment of night vision This opinion springs largely from the observations of Hume and Krebs [1] on male conscientious objectors, and we have little information about the possible effects on pregnant women and their children Experimental studies suggest that slight deficiency of vitamin A early in pregnancy is very harmful to the fœtus Warkany [2] stated that gross maternal deficiency of this vitamin led to abortion, and minor degrees of deficiency resulted in the birth of deformed young, the nervous system was often involved, and hydrocephalus was common It was thought that abnormality of bone growth was primarily responsible for the hydrocephalus [3 4], but recent evidence runs counter to this opinion

Millen et al [5 6] found that young rabbits born to does deficient in vitamin A were constantly hydrocephalic Although stenosis of the aqueduct was found, these workers thought that the hydrocephalus was caused by over-production of cerebrospinal fluid (C S F) rather than obstruction of its circulation or reabsorption Vitamin A was known to cause a fall in the C S F pressure of hydrocephalic vitamin deficient calves [7]

Woollam and Millen [8] have now investigated the effects of vitamin-A deficiency on the C S F pressure in chicks In fifty normal chicks, the average pressure did not change between birth and the age of 150 days, but in thirty-five chicks hatched normally, and subsequently fed on a diet deficient in vitamin A, there was a progressive rise in pressure from an average of 108 mm of water at the age of 30 days to an average of 212 mm water at 125 days A third group of chicks were obtained from hens which had been deprived of vitamin A, after hatching, these chicks were fed on a diet deficient in vitamin A, their C S F pressures rose at the same rate as those of the second group, though the mean pressure was higher at a given age in this third group than in the second It was apparent that the pressure was related to the total (pre- and post-natal) time on a diet deficient in vitamin A rather than to the age of the chicks At necropsy no bony abnormality was found in any of these chicks, and clinically the vitamin deficient were indistinguishable from the normal controls Colloidal carbon was injected into the lateral ventricles of three vitamin-deficient chicks, and at necropsy it was found to have passed freely through to the ventricular system, and to be distributed around the meningeal cuffs of the spinal nerves The ventricles were not dilated in any of them, but Woollam and Millen point out that the choroid plexuses of birds, unlike those of higher animals extend out into the general subarachnoid space, and internal hydrocephalus would hardly be expected They still believe that the over-production of C S F is the cause of the increased pressure, but on the evidence this cannot be regarded as proven

These observations raise important questions Hydrocephalus has occasionally been reported in infants born to mothers deficient in vitamin A[9] In this country it is unlikely that pregnant women will be deficient in this vitamin, but if the experimental findings are applicable to man, the hazards of such deficiency may rank with those of rubella Clearly this possibility must be considered in all cases of fœtal abnormality

EMMETROPIA AND AMETROPIA

THE impression that elongated eyes are myopic and short eyes hypermetropic is largely correct, but the mechanistic corollary—that all emmetropic eyes are of the same length and dioptric power—is far from correct The first breakdown of the concept of fixed optical components in the eye resulted from work by Schnabel and Herrnheiser,[10] who found a range of from 22 0 to 25 0 mm in the axes of 23 enucleated emmetropic eyes Studies by later workers on the other components of refraction—namely, corneal power, lens power, and anterior chamber depth—also showed a range of variation Before the advent of the modern concept of biological variation it must have been difficult to reconcile such variation with the accuracy of structure required in the emmetropic eye, but one by one the frequency-distribution curves of the components of refraction were shown to conform to a normal curve

At first the interpretation of such findings was that emmetropia and the refractive errors resulted from the chance association of the components of refraction[11] This, however was not quite true for the distribution of emmetropia and the refractive errors in the population does not fit a normal curve, there being an undue proportion of emmetropia and nearly emmetropic refractions[12,13] This departure from normal distribution denotes that, though each of the components of refraction shows a normal distribution, they cannot be freely variable, some correlating influence must organise them so that there is a tendency greater than chance to produce emmetropia

Prof Arnold Sorsby and his colleagues[14] have confirmed the normal distribution of the values of axial length, corneal power, lens power, and anterior-chamber depth They have also confirmed that there are more emmetropes and near-emmetropes in the population than can be accounted for by the free association of the optical components of the eye Their measurements of the optical components show that "a wide range of axial lengths, corneal powers, and lens powers is seen in emmetropia, the respective values being 21 to 26 mm, 38 to 48 D, and 17 to 26 D" They conclude therefore that "the emmetropic eye is not the end-result of a haphazard combination of variable components, but a coordinated organ The individual emmetropic eye, like the excess of emmetropes in the general population, is not accidental" They also show that the values of the optical components which occur in emmetropia also occur in ametropia up to ±4 0 D, but eyes with refractive errors greater than ±4 0 D show values of refraction components (especially axial length) greater than those which occur in emmetropia An important qualitative difference is thus shown between ametropias less than and greater than 4 0 D, the former being due to incoordination of optical components within the emmetropic range and the latter being due to components beyond the emmetropic range for which no coordination during growth could have compensated

Sorsby and his co-workers studied the correlations of the optical components and found that the correlation coefficient between axial length and corneal power in emmetropic eyes is as high as −0 877 but with increasing ametropia up to ±4 0 D the correlation becomes progressively poorer Thus in emmetropia the correlation makes it clear that longer eyes tend to have "flatter" corneæ and shorter eyes more "curved" corneæ, while in the refractive errors up to ±4 0 D corneal and axial length are less well adjusted to each other—facts acceptable to anyone with a knowledge of simple optics From these findings and from previous work on corneal refraction and axial length in the developing rabbit eye[15] it is postulated that a "simple mechanical and self-regulating process would appear to underlie the marked correlation between axial length and corneal power" The axial length of the eye in the newborn averages about 16 mm, whereas the full grown eye is about 24 mm long An increase of 8 mm in axial length demands a decrease of refractive power of some 20–30 D if the eye is not to become excessively myopic It is not clear yet how the exact adjustment to increased axial length is achieved, but clearly the simple mechanical effect of increasing the spherical size of the eye must automatically lessen the refraction of the cornea by flattening it The lens also must play a part in the adjustment and Sorsby's team have shown a correlation (−0 488) of lens power with axial length This correlation differs from that of cornea to axial length in that it applies equally in emmetropia and in the ametropias up to ±4 0 D It signifies that, irrespective of refractive error, there is a tendency for long eyes to carry "flattened" lenses and short eyes more "curved" lenses Probably the increasing pull on the zonule as the eye enlarges during growth provides a simple mechanical adjustment

Diminishing corneal and lens curvatures are the two main mechanisms by which the occular refraction is adjusted to the increasing axial length during normal growth It has been shown that each of these mechanisms can be accounted for mechanically by the increasing size of the eye during growth It is unlikely, however, that a mechanical process can be entirely responsible for the exactness of adjustment required Sorsby and his team put forward the interesting hypothesis that, just as the optic vesicle is the "organiser" of the overlying ectoderm into a lens and the overlying mesoderm into sclera and cornea, so the retina (derived from the optic vesicle) may well determine the scleral, lens, and corneal sizes A small retina will have a small overlying sclera, with, therefore, a small curved cornea and a highly curved lens A large retina will be covered by a large sclera, and the cornea therefore must be large and flattened and the lens of large diameter and flattened An emmetropic eye is thus conceived as the result of an orderly adjustment which takes place during growth and which is initiated by the optic vesicle and maintained by the retina

Further understanding of the nature of the refractive errors, and especially of high myopia, depends on elucidation of the hereditary transmission of the optical components of the eye The manner of growth of the eye also requires investigation The valuable report by Sorsby and his team includes accounts of preliminary studies on both these questions

PANCREATITIS AND CORTISONE

ACUTE pancreatitis is usually a non-infective autolytic process precipitated by the release of activated enzymes into the interstitial tissue of the gland The extent and severity of the autolysis seems to determine whether hæmorrhagic necrosis or merely œdema ensues Normally pancreatic enzymes are detectable in the plasma—which suggests that a small amount of the acinar secretion is endocrine and enters the blood-stream direct, although by far the greater part is exocrine and flows into the small intestine What upsets this relationship and initiates pancreatitis remains a mystery Experimentally pancreatitis can be produced in several ways [1]—by rupture of the acini with injections under pressure down the duct, by blockage of the duct and stimulation of secretion, by damage to the pancreatic blood-supply and impairment of local nutrition, and by administration of ethionine (an analogue and anti-metabolite of the amino-acid, methionine) Clinically acute pancreatitis is usually associated with disease of the biliary tract or with acute alcoholism,[2] but in neither case is the mechanism clear Pancreatitis also arises in association with scarlet fever, otitis media, diphtheria, typhoid fever, influenza, trauma, and, of course, mumps [3]

If the diagnosis is sure, medical treatment is directed towards relieving pain, countering shock, correcting electrolyte abnormalities, preventing suppuration, and suppressing pancreatic secretion [4] The mortality varies from 5 to 30% and is highest in those with severe circulatory collapse Some patients have recently been treated with cortisone or other corticosteroids,[4–8] to combat the shock and suppress the inflammatory reaction The shock has been ascribed to adrenal exhaustion, and also to proximity of the pancreas to the adrenals causing adrenal involvement and hence adrenal insufficiency [9] There is no good support for these views, although one of Bockus's seventy-eight patients was found at necropsy to have adrenal atrophy [2] Whatever may be their action, cortisone by mouth or, when there is urgency, hydrocortisone intravenously seem to be of value, and several workers claim life saving results in severely shocked patients [4 7]

In papers which appear on earlier pages of this issue Dr Baar and Dr Wolff describe two cases, and Dr Marczynska Robowska describes a third case, of children in whom acute pancreatitis developed while they were having cortisone or corticotrophin, and the question arises what part, if any, these hormones played in its causation In a girl with asthma, the administration of 25 mg of cortisone was followed at once by pancreatitis, and she died within five and a half hours The other two patients had conditions which could well have been ætiologically significant—one had extensive dermatomyositis and the other had Still's disease, pneumonia, and smallpox Pancreatic lesions can be produced in rabbits by cortisone [10], but pancreatitis has not previously been described as a complication of cortisone therapy in man, and there seems at present to be insufficient reason for discontinuing the assessment of cortisone treatment in acute pancreatitis provided antibiotics are given concurrently

TONSILLECTOMY

IN the war against tonsillectomy the conservatives have so far made all the running [11] The surgeons have remained silent, even though, as Fry [12] points out, over 200,000 such operations are performed annually in the United Kingdom Crooks [13] has now written, with skill and ingenuity, in defence of the operation, and representing, as he does, the Great Ormond Street school, he deserves close attention

He has selected for evaluation a series of 50 doctors' children whose tonsils and adenoids he removed over a period of ten years In the follow-up, he says, a skilled observer—the doctor-parent—has been constantly present to assess the result (Skilled, certainly, but hardly unbiased or dispassionate) The results are presented under headings of the symptoms before operation and the effect on them of tonsillectomy Thus, of 42 children who previously had had tonsillitis and inflamed throat 20 were pronounced cured, 19 improved, and 3 unchanged For all cases and symptoms, 48% were judged cured, 42% improved, and 10% unchanged or aggravated These figures may seem encouraging, but there was no control series, and it is fairly well known that introduction of controls shows that the operation makes no impressive difference [14] Nor does Crooks say how many doctors' children he declined to operate on during the same decade

THE REFUGEES

ALTOGETHER £517 was made available to the fund for medical refugees from Hungary which we opened at the end of last year Nearly all this money was divided between thirty doctors for such expenses as clothes, journeys, and accommodation, but a small sum was devoted to the cost of dictionaries and of gramophone records giving elementary instruction in English In addition, temporary homes were found for several doctors and their families with readers who had offered such help Our Hungarian colleagues expressed warm thanks for this first aid, reaching them as it did before they had begun to find their feet in Britain

---

ON April 15 Dr ROBERT PLATT, professor of medicine in the University of Manchester, was elected president of the Royal College of Physicians of London

THE RESPONSE OF MALIGNANT TUMOURS TO RADIATION

A HYPOTHESIS

CHARLES A. PANNETT
M.D., B.Sc. Lond., F.R.C.S.
EMERITUS PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON

THE only known agent which has any destructive effect on the growth of malignant tumours (apart from the metastases of carcinoma of the prostate) is radiation from radium or from an X-ray tube. Although this action has been known for upwards of fifty years we are still completely ignorant of the manner in which it acts. During all this time attention has been directed almost exclusively to working out appropriate dosage and methods of getting rays of the proper intensity at the site of the growth without damaging neighbouring tissues. Because, in tissue culture, X rays have been proved to kill malignant cells before normal cells, it has been accepted that all we have to aim at, to bring about a cure, is to get rays to the growth in sufficient intensity. For which reason the aid of physicists is regularly called in to calculate the correct dose and to give guidance as to how the rays should be directed to the desired spot. The surgeon, who has been instructed where he must put his radium needles to be effective is not likely, in the event, to get them near the sites recommended by the physicist. Nor is there such exactitude in the biological reactions as rules in the world of the physicist.

Clinical experience with radium needles has clearly demonstrated that the most important area in which to put the radium is in the healthy tissue round the growth. In the tongue the needles are placed as a palisade around the tumour. How strange this is if the greater intensity of the rays is required for the malignant cells. It is true that, if the tumour is at the centre of a sphere of radiating needles, it gets more radiation than the zone in which the needles lie. Since the less radiation the normal tissues get the better, it seems very odd that the needles are not confined to the region of the malignant cells where they are needed. Why is this other method, harmful to healthy tissue, universally used? For the very good reason that the clinical results are better. But it is possible that radiations do not work in this simple fashion. It is quite as sensible to believe that the radiation, acting on normal cells, alters their metabolism so that they produce substances which are antagonistic to the agent which causes cancer (in all probability a virus), or to the cells which have been altered by the cancer agent, and that these substances, being carried by the lymph stream to the area of the growth cause death of cancer cells. If such substances are produced they would seem to be destroyed before they reach the general circulation, because the irradiation of a tumour has no effect upon distant metastases.

EVIDENCE FOR CHEMICAL ACTION

Is there any evidence of such chemical action, apart from its being better to implant radiating foci outside the tumour in healthy tissue? In this connection an observation made by Geoffrey Keynes,[1] when he was carrying out his work on the treatment of carcinoma of the breast by the implantation of radium needles, is enlightening. Keynes's method was to implant radium needles in the breast tissue all round the tumour, but not actually into the growth itself. It was necessary in this pioneer work, to prove that the tumour treated was in fact a carcinoma, and to do this Keynes excised a small piece for histological examination. In the report of his cases he says he gave up this practice because he found that, although the primary tumour disappeared, carcinoma was apt to grow afterwards in the scar resulting from his biopsy. This is a very curious fact. The pieces of growth removed for examination were taken at the time of the removal of the needles—7–10 days after their insertion. The cells of the growth left behind in its original situation were alive at this time but subsequently died. The cells which were transplanted to the skin lived. Both sets of cells had been subjected to the same dose of radiation. And it does not seem that interference with the blood supply of the tumour by radiation could afford an explanation, for although, as is well known, some damage does occur it could not conceivably be as great as in a completely separated graft. The transplanted irradiated cells had so much vigour in them that they survived the period of formation of a new circulation and then grew rampantly.

Let us look at this matter a little closer. The breast is an organ which, as far as its lymphatic drainage is concerned, is quite free from the subcutaneous fat in which it lies. The lymphatics form a plexus round the alveoli of each of the 15–20 segments of which the breast is composed, and from this plexus the lymph collects into ducts which drain into the subareolar plexus from which two large lymphatic vessels run to the axillary glands. That some minor vessels run to the anterior mediastinal glands and to above the clavicle does not alter the fact that, if the lymphatics of the breast are injected with methylene-blue, none of the dye runs into the subcutaneous tissue in which the breast lies.

Now Keynes implanted his radium needles in normal breast tissue. Any chemical products formed as a result of this stimulation would be carried off by the lymphatics of the breast and necessarily bathe the tumour tissue. Let us assume that these chemical agents effect the destruction of the growth, not instantaneously but over some unknown period after withdrawal of the needles. If Keynes, by his biopsy, implanted malignant cells into the skin he would be carrying them away from the healing stream he created by his radium implantation, as none of the lymph of the breast passes through the skin. The cells, not having been killed by the direct impact of the rays, would be free to grow in their new situation.

This observation by Keynes (which he did not comment upon except to say that he abandoned biopsies because of it) would be explainable if cancer is cured by X rays as the result of a response of normal tissues to radiation. It is at least a possibility to which attention might be fruitfully turned.

Further support for this view would seem to be afforded by the frequent failure of a second dose of X rays when a recurrence has taken place at a site previously subjected to radiation. The normal tissues here have been damaged so that they are unable to respond to radiation, while the new vigorous cancer cells grow unaffected.

Little is known of the chemical effects upon the tissues of exposure to X rays, and it is most remarkable that intensive research has not been undertaken on this aspect of cancer treatment. There would be much to explain if we accept this chemical hypothesis. Why, for instance, is there no general action of the drug? There can be several explanations of this: it may, for instance, be produced in very small quantities and quickly diluted or destroyed in the blood stream. But the absence of distant action should not hinder us from a chemical investigation of what takes place at the irradiated site, and knowledge gained of this may point the way to the attack on metastases. That a local store is set up from which the substance is slowly released is indicated by the fact that the destructive process of the cancer goes on after the cessation of the radiation.

---

[1] Keynes, G. *Brit. J. Surg.* 1932, 19, 415.

SUGGESTED RESEARCH

The testing of thousands of drugs has been without result Here there is something happening, here are tumours actually disappearing, in certain circumstances melting away before our eyes An investigation of what is taking place would surely be more likely to give results than the random testing of drugs or intensifying our efforts to get shorter and shorter waves in narrower and narrower areas—a line of research which has been singularly unproductive over many years

In planning such researches several considerations come to the fore Because of the element of time it is obviously best to work with implanted tumours in small laboratory animals, and it must be ascertained first whether the particular tumour we choose for experiment can be caused to disappear by exposure to X rays Then a tumour must be selected that will give as near as possible 100% positive results on transplantation No deductions could be depended upon with tumours showing great biological variations This is one of the difficulties hampering such work

The chemical extracts of tissue can be prepared by using lipid solvents in some cases and aqueous in others Heterologous extracts of this kind can be quite harmless on injection if protein be removed But by eliminating proteins we may be discarding the very agents we are looking for Then we are quite *ignorant as to whether the wanted* substance is thermo labile—another severe handicap to technique and the maintenance of sterility The particular tissue which should be extracted may be of great importance, so various tissues will have to be tested

The method of radiation needs much consideration, for the quantity of energy needed to produce chemical changes such as we want is quite unknown If a β radiator be used the problem of getting the whole volume of substance under the influence of the electrons must be solved

Such are the questions for which answers have been sought in some researches by Dr Arthur Compton and myself But the whole problem is a very large one, and I do not see, apart from the unlikely lucky hit, that an early solution can be arrived at unless such researches are undertaken on a considerable scale and by numerous experimenters To me it seems well worth pursuing any new path in the baffling enigma of cancer

PRICE OF PROPRIETARY PREPARATIONS

THE Government have accepted in principle a scheme for regulating the price of the 4000 proprietary preparations which the Joint Committee on Prescribing recommended should be available for National Health Service patients subject to satisfactory price arrangements with the manufacturers These drugs account for about 90% of the cost of all proprietaries prescribed under the health service—£23$^1/_2$ million out of a total of £25$^1/_2$ million The scheme has been negotiated by the Health Ministries and the Association of British Pharmaceutical Industry It will run for a trial period of three years

Under the scheme manufacturers will regulate their prices voluntarily according to the following principles

The price in the United Kingdom will not exceed that which the product commands in adequate volume in overseas markets in face of international competition

When a product is not exported in significant quantity, if an identical non proprietary standard drug is available in the U K the price of the proprietary shall not exceed the price of the standard drug

If it is impossible to apply either of the above provisions, a maximum price may be determined by using a detailed formula comprising (i) an ingredient allowance based on recognised trade prices and (ii) processing and packaging allowances according to a schedule covering different types of product

The prices determined by these principles will be maximum prices Immediate effect will be given to price reductions that result from the application of the scheme, but if the permitted maximum is higher than the existing price the existing price will not be increased on that account The scheme also provides that a manufacturer may instead negotiate "a fair and reasonable price" with the Health Departments

The scheme is not designed to reduce prices generally but to curb excesses where they exist While its effect on National Health Service costs is not expected to be large, a saving of up to £750,000 a year is thought possible To meet the industry's need to finance research and development no product will come under the scheme during the first three years of the product's life

THE ROYAL COMMISSION

Terms of Reference and Procedure

AT a special comitia of the Royal College of Physicians of London on April 11, Sir Russell Brain, the president read the answers he had received to questions he had asked the Prime Minister He also gave an account of his meetings with the Royal Commission and with its chairman, Sir Harry Pilkington After hearing his statement the college decided that they wished to cooperate with the Royal Commission

The Prime Minister's Answers

Question 1

In clause "A" of the *Royal Commission's terms of* reference the term "other professions" is a vague one, since today there is no agreed definition of a profession Apart from this it is difficult to see why the incomes of other callings should be treated as irrelevant to the economic and social status of the professions Will the Royal Commission be free to take into account incomes earned not *only* in the "professions," but also in commerce and industry, both as salaries and wages—a point of obvious importance in relation to recruitment to medicine?

Answer—It must be left to the commission to decide what interpretation should be put on the words "*other* professions," but I feel sure that they would not wish to adopt any narrow interpretation or refuse to consider any callings which might be cited in evidence *before* them

Question 2

Clause "B" begins "What, in the light of the foregoing, should be the proper current levels of remuneration?" This has been interpreted as meaning that the Royal Commission would have to limit itself to a consideration of the matters set out in clause "A" The fear has been expressed that this is unduly restrictive, and that the Royal Commission having heard evidence on other matters would find that its terms of reference precluded its consideration I have in mind the matters referred to the Spens Committees, namely, "the desirability of maintaining in the future the proper social and economic status" of general medical practice and consultant and specialist practice, and their "power to attract a suitable type of recruit to the profession" Hours of work and the responsibility of the work undertaken are also important considerations Would the Royal Commission be free to make recommendations "in the light" not only of clause "A" but also of any other evidence which the medical and dental professions might wish to present?

Answer—The medical profession would be free to bring points of *this kind to the notice of the* commission, and there is nothing in the terms of reference to prevent the commission from considering them Indeed, in order to satisfy their terms of reference they would have to consider some at any rate of them As in the case of other evidence it would be for the commission to decide what weight to attach to them

Question 3

It would seem that any recommendations about future remuneration should take into account how the present levels of remuneration have been arrived at, *and* this would include a discussion of the recommendations of the Spens *Committees and the Danckwerts* award Would the doctors and dentists be free to put before the commission their view that the remuneration of the professions, now and in future, should be determined on the basis of the Spens recommendations and the Danckwerts award?

Answer.—I feel sure that the commission will be prepared to receive and to take into consideration any expression of views which the medical and dental professions put before them as being in their opinion relevant to the commission's work.

Question 4

On March 11 in the House of Commons, Mrs Jeger asked the Minister of Health "whether it will be within the terms of reference of the Royal Commission on doctors and dentists remuneration to consider the abolition of merit awards." The Minister replied: "The Royal Commission will normally be concerned with levels of remuneration, not with methods as such. Whether or not questions such as that referred to by the honourable member are within its terms of reference must rest with the commission itself to decide." I should be glad to know whether the commission has reached a decision on this point, and, if not, when it will have done so.

Answer.—I cannot say what if anything the commission have decided; if it becomes possible for them to make any statement on the matter which you raise, they will no doubt do so themselves. But I imagine that they would wish to hear evidence and to make substantial progress with their work before arriving at a view as to whether and if so how far, their main task of recommending "proper current levels of remuneration" requires them to consider the particular matter which you mention.

Question 5

There is a strong feeling in the medical profession that our colleagues in the public-health service should not be excluded from the scope of any review of remuneration. Do the terms of reference of the Royal Commission include them?

Answer.—The remuneration of doctors employed by local authorities is excluded from the scope of the Royal Commission's recommendations but any claim on their behalf through the usual machinery would necessarily be considered in the knowledge of any recommendations of the commission.

Having begun his letter by saying that "interpretation of the terms of reference is a matter for the Royal Commission and I cannot in any way formally commit it," Mr Macmillan concludes with the statement that he has consulted Sir Harry Pilkington, who agrees with his replies.

Statement by the Royal Commission

On April 12 the Royal Commission issued a statement on how they have decided to proceed:

1. The Spens reports and the Danckwerts award will be studied by the commission, and also the reports of any other commissions and committees in so far as they are relevant to the circumstances of the medical and dental professions and to the relationship of those professions to the community as a whole.

2. The commission will bear in mind the need for maintaining a proper level of recruitment to the medical and dental professions in competition with other callings, and will consider evidence as to conditions imposed by the nature of the work.

3. The phrase "other professions" will be interpreted widely so as not to exclude, for example, science and other graduates in industry at all levels.

4. The commission are not asked to recommend remuneration for doctors and dentists employed by local authorities, but these doctors and dentists are among the "other members of the medical and dental professions" on whose remuneration evidence will be received for purposes of comparison.

5. "Other connected occupations" cover a wide range of persons, including on the one hand hospital administrators, and on the other nurses and medical auxiliaries whose remuneration will be considered with special reference to differentials.

6. The commission will in the light of all this and any other relevant evidence recommend such "current levels of remuneration" as appear to the commission to be justified.

7. The *commission's duty to recommend current levels* of remuneration calls for recommendations covering, for example, average incomes and the desirable spread between extremes; but it does not call for the construction of detailed schemes of distribution.

8. After consideration of the desirable current levels of remuneration for doctors and dentists, the commission will consider whether, and if so what, arrangements should be made to keep that remuneration under review.

In a separate notice the Royal Commission are asking all interested persons or organisations to offer evidence. "Preliminary inquiries have shown that the preparation of this evidence will take some of the bodies concerned considerable time. The commission are anxious to complete their task with the utmost speed consistent with thorough examination of all the relevant issues, and hope that all written evidence and submissions to the commission will be in their hands within the next three months."

Public Health

The Salford Radiography Survey

IN 1953, an intensive mass miniature radiography (M.M.R.) survey was made in Salford[1] and some of the new points made in a report on it by Hughes[2] will be useful in planning future surveys.

A feature of the survey was a special canvass of a random sample of the population, urging them to attend. The response was 29.5% (i.e., about the same as in the general population of adult Salford residents) when a commercial firm of canvassers was used, but 42.7% when the canvassing was done by health visitors, who more often elicited a family history of tuberculosis. The health visitors could not be spared for further canvassing from their other duties—one of the most important being to *supervise tuberculous patients* in their homes.

Persons in the random sample were asked various questions. Most preferred evening M.M.R. sessions, and thought that leaflets (which were sent to all householders) were the most effective form of publicity. But Dr Burn, the medical officer of health, was impressed rather by the value of personal interviews. Attendances for radiography were greatest in the early weeks of the campaign: enthusiasm fades after six weeks. When the numbers began to fall off, professional canvassers were used to rekindle it, but the response was slight. In general the response was regarded as disappointing, and this was thought to be due to the many previous selective surveys in the city.

As usual in mass radiography, the highest prevalence of tuberculosis was found in patients specially referred by the family doctor, and a substantial number of tumours was also detected. The group with the highest prevalence of tuberculosis was men of 45–59—in which the response was poor. In various surveys it has been found that the bigger the proportion of the population responding, the higher the number (per 1000 radiographed) found to have active disease. It is estimated that there may be 150–160 undetected cases in Salford, more than half of them with positive sputum.

As a result of the survey, there was a peak in the incidence of new cases found in Salford in 1953; since then the number has fallen sharply, and it is now below the average for the 21 largest towns of England and Wales. As in the country as a whole, about 21% of deaths from respiratory tuberculosis in Salford in 1955 were in cases not previously notified. The number on the clinic registers is rising by 2–3% a year, though the death-rate continues to fall. The record of patients recovered and erased from the register is said to be better than in most towns.

A list of priorities for the most efficient use of M.M.R. is given by Dr Burn.

Medical Education

THE STUDENT AND SEX EDUCATION

BERNARD SANDLER
M D Manc , D M R , D Obst
MEDICAL OFFICER IN CHARGE, INFERTILITY CLINIC,
MANCHESTER JEWISH HOSPITAL

THE student and his problems are sometimes discussed as though he were a separate species of mankind created de novo, already 17 years old ! It seems to be forgotten that he is an adolescent, very recently a child, who often has just left the security of the parental home for the first time He is in fact especially likely to have emotional problems, since he commonly combines high intellectual equipment with inadequate emotional development, compared with the average adolescent in commerce or industry whose emotional adjustments are usually made earlier (Grant 1954, Logan 1954)

He is equally likely to have problems of sex The combination of emancipation from parental authority, a fevered romanticism, and an urge for erotic adventure may well throw his emotional stability out of gear In the case of medical students, the study of anatomy and physiology induce a mechanistic approach to matters which are primarily spiritual and psychological The student whose sex education has been inhibited or distorted by his home background can get into very considerable difficulties, for he may already have serious emotional tensions when he arrives at the university Parnell (1951) found that 1% of all undergraduates at Oxford were suffering from some mental disturbance, and of all those absent through illness for a full term over half were mentally ill Malleson (1954) said that 10% of all students in residence in any given year could be classified as "distressed students," and that the suicide rate was higher than in a similar age group in the general community Hence we cannot discuss sex education for the student without reference to the formative influences in his life before he reaches the university Sex education does not begin with the formal talk by father to son as pictured in Victorian times It starts at a very early age by unconscious absorption of the attitudes adopted by those handling the child, and it continues throughout life It is much more than a description of the genitalia and the sex act it includes the whole relationship of man and woman with each other Thus the student may enter medical school with only the vaguest idea of how to deal with manifest problems of sex and marriage which are so important to the welfare of so many patients , and of course he is still less likely to recognise these problems when they are concealed as symptoms to which his teaching has paid no attention

It is strange therefore that though every student during his training is expected to know how a gastrectomy and an arteriogram are done—operations which none will ever have to perform without further postgraduate training—sex and marriage are touched on only briefly as an incident in clinical teaching His instruction is still too often based on organ dysfunction rather than on the treatment of the patient as a whole , and where the two patients comprise the single entity of a marriage, such an approach is even more hopeless As a rule, the illness encountered in a clinic is seen from the viewpoint of the specific organs in which that clinic specialises rather than as a syndrome of the whole person The consequence is that most doctors who acquire any knowledge of sex by the time they graduate, do so, not by organised instruction in the subject but rather by personal enterprise Not all doctors may be suited temperamentally for giving advice on this subject , but at least they should receive sufficient basic training to enable them to recognise not only their patient's difficulties but also their own inhibitions

In an infertility clinic such as mine, where husbands and wives are seen together, and where an attempt is made to assess the marriage rather than one partner of it, many cases (which are referred apparently solely for sterility) are in fact found to have psychodynamic problems of marital disharmony which have unfortunately not been recognised either by the patient or the doctor Worse still, advice has been disastrous in certain cases when given by a doctor insensitive to, or untrained in, the recognition of these emotional problems This consideration led me to inquire whether medical education is adequate in these matters

Instruction at Medical Schools

To ascertain the present position of medical teaching I asked forty seven medical schools in Great Britain and abroad to tell me what instruction is given in the following subjects

1 The physical and psychological background of normal coitus and conception
2 Contraception
3 Sexual maladjustment and marital dysharmony

Thirty six schools sent replies—twenty-four in Britain and twelve abroad Of these, only two said that no instruction was given at all, one saying that it "was not desirable for students" But only five provided formal lectures on coitus and conception, though in a further six these topics were discussed in clinics In twelve, one formal lecture was given on contraception, and in another seven clinical instruction was arranged In seven, lectures were given on sexual maladjustment and in another five it was discussed in the clinics Finally, the psychological problems of the background to marriage were discussed by none in formal lectures, but in fourteen these were mentioned in a general way during the course of clinical teaching These figures suggest that probably less than half of the students at these schools have had anything like adequate instruction before they enter their professional life

To compare the opinions of the students with those of their teachers, inquiry was made of graduates from five universities who had qualified in 1951–53 The teachers at these particular universities had informed me that such instruction was included in general clinical teaching, though not in systematic lectures, and they were satisfied that enough was taught But at only one of the five was the training regarded as satisfactory by the graduates At the four others, all the graduates said that they were dissatisfied and had in fact very little or no instruction

We may compare this with the replies given to Ingleby (1952) on the teaching of teachers and clergy, who also have an influence on family life in the community

Teachers

Of fifty-one training-colleges and seven university education departments, all except three deal with sex education The courses of instruction were divided by Ingleby into three groups (1) Fifteen covered only anatomy and physiology and there were no other lectures (2) Twenty-one discussed the psychological implications and gave training for sex teaching in a broad sense Possibly this was done with an academic rather than a dynamic psychological approach, but at least an attempt was made to discuss emotional adjustments and sex relationships in terms of the students' own personal adjustments (3) In ten, attempts were made to give a broader approach to sex in the wider setting of marriage and the family , in some cases this included a completely separate course of lectures

Clergy

In sixteen out of twenty Church of England colleges, a course of 9–12 lectures with special references to the ethical and psychological aspects of sex and marriage was given Other denominations gave some training on marriage but none was as adequate as the Church of England training

From this it seems that doctors are the least equipped of the three professions dealing with these concerns of everyday life. If in fact the main obstacle (apart from inertia) is the overburdened curriculum, surely the time has come to discard some of the traditional items in favour of what is of increasing importance in the modern world.

This is not the place to outline all the psychosomatic syndromes likely to be encountered either in disguise or as diagnoses which the patients themselves make, such as impotence, frigidity, and vaginismus. Such cases should obviously be treated by those who specialise in them; but it is astonishing how many such patients are still treated with tonics, sedatives, or just "reassurance." Once rebuffed they will rarely return to the same doctor for advice on such a matter, and when their difficulties continue for years they eventually become hopelessly incurable.

My purpose is simply to state a case for the improvement of medical education on these topics, and to put forward suggestions for incorporation in the medical curriculum.

Recommendations

The student should receive instruction in sex education and be helped to solve his own personal problems. If he can understand himself, he is better able to understand others: an emotionally maladjusted student will be a bad student and a worse doctor. Each university should have an adviser for students, to whom they can bring their personal problems. He would combine knowledge with understanding based on experience. (An adviser whose advice is academic and who cannot perceive the unasked questions in the student's mind may be worse than no adviser at all. Equally, the other type of adviser who gives the student a slap on the back and the hearty advice to "go out and get a woman" may also do serious emotional damage.) Undoubtedly advisers with the right personal qualifications are scarce, but even so it seems that in many universities little attempt has ever been made to find them. Here the local marriage guidance councils could help.

Systematic lectures on the physiological and psychological background of normal coitus should be given to senior medical students. The relation of sex to the larger sphere of family life and human relations should be explained, and a sense of perspective given of its relation to right living. (At many schools such subjects as marriage guidance, premarital preparation, and marital dysharmonies do not seem to be covered.) Systematic lectures should also be given on sexual maladjustments, coital technique, impotence, vaginismus, &c., by someone experienced in these subjects. Each university library should contain a selection of books and pamphlets on all these subjects.

Instruction in contraception is indicated—both theoretical (with a film) and practical (by attendance at Family Planning Association centres).

Lectures on the spiritual and psychological background to marriage, with special emphasis on normal relationships, could well complete the course.

Lists of suitable books on sex and marriage problems may be had from the National Marriage Guidance Council, 78, Duke Street, London, W. 1, or the "Alliance," 238, Edgware Road, London, W. 2, free of charge.

I should like to express my thanks to those University teachers who were kind enough to reply to my questionnaire.

In England Now

A Running Commentary by Peripatetic Correspondents

It all started with a seductive brochure from the Central Council for Health Education introducing the first of a series of make-it-yourself pegboard displays to peddle preventive medicine in the market-place. A wave of nostalgia swept over my desk. Far back in school days I turned the odd sixpence carving model *Dreadnoughts*; my undergraduate conception of an embryo in plasticine was an artistic gem, albeit introducing a revolutionary portrayal of the development of the human gut; post-war parental responsibilities saw Sunday afternoon struggles with balsa wood and dope in that era of model aircraft kits. When plastics and puberty brought self-help to the young engineers, I retired from the bench to enjoy presbyopia and the caress of losing consciousness after lunch. So it was a burst of boyish enthusiasm that ordered the pegboard display set. Like all good secretaries, Miss McDour has a depressing flair for pointing out my limitations. Monday morning found her viewing a huge parcel with extreme distaste before she flounced away to submerge herself in the typing pool. The chief clerk's bald head peeped round the door and winked. The office boy came to collect the wrappings, and the caretaker brought elevenses. Our quartet knelt down on the floor to sort out the bits. There were three sheets of instructions, including the old familiar command to have at hand scissors, razor-blades, sharp knives, strong glue, and a knitting needle. The office boy startled me by producing a nicely mounted razor-blade and a flick knife from his pocket. He knew where to borrow a knitting needle; his girl friend on the telephone switchboard is having a race with time to complete her trousseau, but she rallied to our call. The great idea was to produce a three-dimensional effect of a couple of toddlers surrounded by the gin-traps of adult life, symbolised by boxes of matches, dangerous drugs and scheduled poisons, fireplaces and saucepan handles, surmounted by the heart-cry caption "Are they Safe at Home?"

I should never have let the chief clerk use the flick knife. He sliced a chunk out of his thumb and spurted arterial blood all over the saucepan. A tourniquet fixed him, but the model dropped below food-hygiene standards. The office boy got more glue in his hair than on the cardboard; at least it stopped his forelock flopping. By lunch-time we had finished cutting out. I moved my desk over a hole in the carpet. At 2 P.M. we returned to battle. The junior typist, not long graduated from dressing paper dollies, joined the party. She put some cold cream on my hand after we had mounted the matches display and learnt that these new glues are inflammable. Pity about her eyebrows, but she can use a pencil. The chief clerk consoled himself with a couple of aspirins from the poison tray. The caretaker alone emerged unscathed. The job looked very pretty. We creaked ourselves proudly up from the floor at 5 P.M. Miss McDour minced frigidly to my desk with her calculation that our day's labour had cost the corporation well over £10 in salaries, about twice the price of the display set, and just think of a thousand local-government offices frittering away their man-power and knitting needles. But bandaged, burnt, and blistered as we were, we little band of health educators went off rejuvenated to the safety of our homes.

* * *

Recently I met a young couple who had been guests at the Medical Research Council's Common Cold Research Unit at the Harvard Hospital, Salisbury. They were enthusiastic, and said that they would like to pay another visit, taking their ten-year-old child with them. I expressed doubts on the wisdom of this, but later I found my thoughts turning to the possibilities of research in infectious diseases in childhood. What about a Mumps Prophylaxis and Treatment Research Unit for prepubertal males? Parents who had apparently failed to indoctrinate their boys with the mumps virus by close contact with their stricken school-friends, could sign them up for a stay at Fat Face Farm, or Parotitis Place. The major service would, of course, be to induce an attack of mumps in delightful surroundings. Terms would depend on whether the patient stayed only until the onset of his

THE STUDENT AND SEX EDUCATION

Bernard Sandler
M D Manc, D M R, D Obst
MEDICAL OFFICER IN CHARGE, INFERTILITY CLINIC,
MANCHESTER JEWISH HOSPITAL

The student and his problems are sometimes discussed as though he were a separate species of mankind created de novo, already 17 years old! It seems to be forgotten that he is an adolescent, very recently a child, who often has just left the security of the parental home for the first time. He is in fact especially likely to have emotional problems, since he commonly combines high intellectual equipment with inadequate emotional development, compared with the average adolescent in commerce or industry whose emotional adjustments are usually made earlier (Grant 1954, Logan 1954).

He is equally likely to have problems of sex. The combination of emancipation from parental authority, a fevered romanticism, and an urge for erotic adventure may well throw his emotional stability out of gear. In the case of medical students, the study of anatomy and physiology induce a mechanistic approach to matters which are primarily spiritual and psychological. The student whose sex education has been inhibited or distorted by his home background can get into very considerable difficulties, for he may already have serious emotional tensions when he arrives at the university. Parnell (1951) found that 1% of all undergraduates at Oxford were suffering from some mental disturbance, and of all those absent through illness for a full term over half were mentally ill. Malleson (1954) said that 10% of all students in residence in any given year could be classified as "distressed students," and that the suicide rate was higher than in a similar age group in the general community. Hence we cannot discuss sex education for the student without reference to the formative influences in his life before he reaches the university. Sex education does not begin with the formal talk by father to son as pictured in Victorian times. It starts at a very early age by unconscious absorption of the attitudes adopted by those handling the child, and it continues throughout life. It is much more than a description of the genitalia and the sex act: it includes the whole relationship of man and woman with each other. Thus the student may enter medical school with only the vaguest idea of how to deal with manifest problems of sex and marriage which are so important to the welfare of so many patients, and of course he is still less likely to recognise these problems when they are concealed as symptoms to which his teaching has paid no attention.
